

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 23 1946

British Medical Association PROCEEDINGS OF COUNCIL

Wednesday, November 6, 1946

A meeting of the Council was held on Nov. 6, with Dr. H. Guy Dain in the chair. The deaths of two former members were reported, namely, Dr. C. G. Gooding, of West Liss, and Dr. Ashton Street, of Crowborough, and votes of condolence were passed. Mr. Zachary Cope was appointed representative of the Association on the Central Council of Physical Recreation in place of the late Sir Kaye Le Fleming, and Dr. L. D. Callander was appointed to fill a vacancy in the B.M.A. directorships on the board of the British Medical Bureau.

In conformity with a resolution of the Annual Representative Meeting, the Council agreed to set up a committee to investigate and report upon the treatment and care of the elderly and infirm. In addition to several members of Council, it was decided to request certain people from outside the Council to serve on the committee.

The Insurance Capitation Fee

Dr. E. A. Gregg, chairman of the Insurance Acts Committee, in presenting his committee's report, recounted the course of events in connexion with the insurance capitation fee, including the conversations with officers of the Ministry, and said that a meeting with the Ministry on the reference of the Spens Report to the current capitation fee was to take place on Nov. 13. The Annual Conference had endorsed the action of the committee, and he was satisfied that they had behind them the solid support of doctors in insurance practice.

General Practice Committee

The following recommendations of the General Practice Committee (Dr. S. Wand) were agreed to without discussion: that the Minister of Health be asked to use his powers to urge local authorities to give priority to medical practitioners in the allocation of housing accommodation; that when a practitioner is asked by an insurance company or solicitor to be present at the examination of his patient by another doctor, the practitioner should negotiate an appropriate fee with the company or solicitor as the case may be; that the exhibition of "doctor" signs on cars is no longer desirable or necessary, and that steps be taken so to advise the profession.

It was agreed to set up a special committee to review and report on the working of the Coroners Acts, to consist of six members appointed by the General Practice Committee, two by the Coroners' Society, and the chairman for the time being of the Pathological Group Committee or his nominee. The Council endorsed the committee's proposal that further representations should be made to the War Office for an increase in the remuneration of civilian medical practitioners employed by the War Office for the medical examination of military personnel on release.

Priority Milk Certification

Dr. F. Gray called attention to the statement issued by the Ministry of Food which appeared in the *Journal* of Nov. 2 (p. 661). It contained, he said, the gravest possible accusation against a whole section of the profession. What it amounted

to was that, practically, out of every three milk certificates one was dishonest. He submitted that the difficulty was not due to the dishonesty of certifying doctors but to the fact that the people of this country, having hesitated to claim their full rights in matters of this sort during the war, felt such hesitation no longer now that peace was restored, and doctors, faced with justifiable claims for special diets, could do no other than give the necessary certificates. There had been no consultation with the Association before this statement was issued, and this attack had been made on medical practitioners, who were being used as a scapegoat for the incompetence of a Government department which had miscalculated the amount of milk required for both priority and ordinary consumers. He hoped also that the Council would express its regret that a specialist body, the Food Rationing (Special Diets) Advisory Committee, should have expressed an opinion without making itself fully conversant with the facts.

Dr. A. T. Rogers said that though he felt that this matter had been handled badly, and the Association should certainly have been consulted, he hoped no resolution would be passed which would result in the further cutting down of the milk supply to the normal population because of this rise in the amount of milk consumed by those who received priority certificates. Dr. H. M. Golding said that, while keeping strictly within the schedule, the medical profession could order a great deal more than it actually did at present. For example, under Schedule 2 (a) an active worker, during the first six weeks of his incapacity, could draw one pint of milk daily, which was not usually done. Mr. A. S. Gough pointed out that, under the present regulations, on a certificate of peptic ulcer two pints daily were allowed, and this went on indefinitely because there were no means of saying that at a certain point the man needed only one pint. Dr. Wand suggested that the increase was largely explained by men coming back from the Forces with gastric trouble which redeveloped in civil life.

Dr. J. A. Brown hoped that when the Association went to the Ministry on this subject they would not suggest many economies or a limitation of the conditions for which priority milk was given. The case of old duodenal ulcer might be cut down to one and a half pints or even one pint, but the case of new duodenal ulcer should not be given less than two pints. The suggestion that invalids and old people should be asked to go without milk was scandalous so long as such large quantities of milk were allocated to canteens and milk bars frequented by healthy persons. Dr. H. H. D. Sutherland said that the question of reducing the quantities allowed might very well be left to general practitioners, but he resented very strongly the statement that general practitioners were lax when in fact many of them were taking special precautions—including radiographic examination—to determine whether in a given case there was an ulcer which justified this extra allowance. The following resolutions were passed:

That the Council strongly protests at the action of the Minister of Food in issuing a public statement in which the medical profession is blamed for improper certification without proper evidence and

without consultation with the B.M.A., the body which since 1941 has been consulted by the Ministry on this subject.

That the Minister be informed that the B.M.A. will be glad to confer with him on the milk arrangements generally and on any steps he proposes to secure the Minister's objective of reducing the consumption of milk by invalids.

That the Council express to the Medical Research Council its regret that the Food Rationing (Special Diets) Advisory Committee should have made to the Minister of Food a statement implying that the medical profession is not maintaining a high standard of accuracy in its certification, there being no valid evidence to support such an allegation.

Public Health

It was agreed, on the recommendation of the Public Health Committee (Dr. J. Fenton), to appoint a special committee to formulate for submission to the Ministry of Education proposals for the revision of the scale of fees for medical treatment of school-children, embodied in Ministry of Education Circular 102.

The chairman of the committee reported that the local authority associations were proposing to hold discussions with the employers' side of the National Joint Council for local authorities' professional and technical services on the question of salaries of chief officials. The committee had decided that if the Association were invited to these discussions it should reply that it was a party to the Askwith scales relating to the public health service as a whole, and therefore could not participate in separate negotiations, but would be willing to send observers to the conference. The committee had also some evidence that the interim Askwith scale was being regarded as a future permanent scale for the public health service, and it was felt that this erroneous impression should be corrected. It was proposed, therefore, to circulate the proposed new scales for whole-time hospital and public health medical officers to all medical officers of health with appropriate explanations, and with a request that they should make known to their colleagues and to their authorities the existence of the proposed scales and the purpose for which they have been formulated.

The committee brought forward a recommendation that a request be made to amend the Medical Practitioners (Fees) Regulations, 1940, to provide that the minimum fee for attending a full confinement under local authority arrangements should be five guineas. This was in conformity with a resolution of the Annual Representative Meeting. To make it correspond more closely with the phraseology of the regulations, the committee proposed to add after "full confinement" the words "and subsequent visits during the first fourteen days inclusive of day of birth." The recommendation was agreed to, and the committee undertook to consider further the whole question of the fees to be paid to practitioners in midwifery cases.

The "Closed Shop"

The question of the "closed shop"—an issue which has arisen in consequence of the repeal of the Trade Disputes Act, 1927—arose on the reports of the Public Health Committee, the Liaison Committee of the B.M.A., and the Royal College of Nursing. Dr. R. W. Cockshut said that no one appeared to know exactly what the "closed shop" meant, but it was possible that it might affect some members of the medical profession. It was most undesirable that there should be any compulsion by local authorities on their medical officers to join any medical body, whether trade union or professional association, and if any man in the local authorities' health services was prepared to stand out, the Association ought to support him with all its power.

The Secretary explained that there were three kinds of resolutions passed by local authorities on this subject: (1) Requiring employees to be members of a trade union or professional association; (2) requiring employees to be members of a trade union, but accepting membership of "Nalgo" as satisfying the condition, "Nalgo" being a certified but unregistered trade union not affiliated to the T.U.C.; and (3) requiring employees to belong to a trade union affiliated to the T.U.C. Dr. J. A. Pridham said that they could see in this the implications for a future health service. To compel members of the profession to join an organization which must be a trade union—which the British Medical Association could never be—would be a very insidious way of controlling the profession. He felt that

they must take their stand now without any equivocation and have nothing whatever to do with it.

The Chairman of Council said that they properly objected to anybody's being forced to join any organization, even including the B.M.A. He also pointed out that the effect of any resolution of that kind would be the non-acceptance in the *Journal* of advertisements of public authorities which made any stipulation as to membership of any professional body (other than a medical protection organization), and a decision would have to be taken to stand by any member who suffered as a result. The Council decided to appoint a committee to examine the implications of the whole subject and to report. The members of the committee appointed were Drs. G. F. Buchan, O. C. Carter, R. W. Cockshut, J. Fenton, R. Forbes, F. Gray, J. A. Ireland, and J. A. Pridham, with the Officers of the Association. It was stated that no policy had been laid down by the Representative Body, though the subject was debated at the A.R.M. in 1925.

Hospitals

On the recommendation of the Hospitals Committee (Mr. R. L. Newell), it was agreed to recommend to voluntary hospitals that, without prejudice to future arrangements under the National Health Service, the visiting specialist staffs of such hospitals be paid salaries during the interim period assessed on the basis of five guineas a session, and to urge the Ministry of Health to provide financial assistance to the extent necessary to enable the hospitals to adopt this course. Mr. Lawrence Abel urged strongly that a session should be closely defined. In order to safeguard themselves and their colleagues, a session should be limited to two hours. He asked that that point be pressed upon the hospitals. Mr. A. M. A. Moore said that the whole question of the remuneration of consultants in a State medical service was coming forward, and the new Consultants and Specialists Committee had appointed a subcommittee to go into the question. This whole matter, including the question of the length of session, might very well be referred to that subcommittee.

Mr. Newell stated that the Hospitals Committee had now recorded its opinion that the imposition in the terms of service of a resident hospital officer of any condition relating to future practice in the area served by the hospital was undesirable. Dr. H. R. Frederick disagreed with this decision and moved the reference back of the paragraph in which it was embodied, and this was seconded by Dr. W. D. Steel. Dr. Gray supported the case for reconsideration, and thought that the General Practice Committee should also look into the subject and consider its bearings in different areas. Mr. Lawrence Abel wanted it referred back for a different reason. In his view there should be complete freedom, and he desired to see a strong recommendation brought forward to that effect.

The reference back was carried by 15 to 13.

Consultants and Specialists

Mr. A. M. A. Moore, as the new chairman of the Consultants and Specialists Committee (formerly the Special Practice Committee), brought forward a report containing seven recommendations, all of which were agreed to. Before putting them he paid a tribute to the long service of Prof. A. H. Burgess as chairman of the committee.

The first recommendation was to approve certain new rules for the government of Groups and for consultants' and part-time consultants' rolls to replace the rules which had been previously approved by the Council in 1938 and revised in 1939. Consideration had been given to these rules in view of the change of status of the representative committee of consultant members of the Association. Another recommendation was that a letter be issued to all consultants and specialists summarizing the proposals for the National Health Service which concerned consultants and specialists, with particular regard to certain points—e.g., that consultants and specialists will become salaried officers of regional bodies, undertaking all their hospital work in hospitals owned by the State; that only those specialists who enter the Service will be permitted to undertake the treatment of patients in hospital, whether in the public or private accommodation; and that there is no real freedom of choice for the consultant or specialist faced with the decision whether or not to enter the new Service.

The Secretary drew attention to a House of Lords amendment which had been accepted:

The Minister may allow any medical practitioner serving, whether in an honorary or paid capacity, on the staff of a hospital . . . to make arrangements for the treatment of his private patients.

He said that the significance of those words was not clear, and they were capable of more than one interpretation. Mr. Lawrence Abel suggested that representatives of consultants and specialists should join in a letter to encourage their colleagues who were isolated and perhaps not very well informed in these matters. The recommendation of the Committee was agreed to.

Another recommendation which was agreed called for better facilities for necropsies undertaken at the request of coroners. It was also agreed, at the instance of the Committee, to request that, in connexion with the planning of the post-war organization of the medical services of the Armed Forces, dermatology be recognized as a separate specialty divorced from venereology.

Practitioners with Heavy Financial Commitments

Dr. H. H. D. Sutherland moved:

That in order to ensure the loyalty of members of the Association urgent consideration should be given by the Council to the position of practitioners with heavy financial and educational commitments.

He was concerned with the difficulties of the young or middle-aged practitioner in his area, a man perhaps who had had to borrow money from his banker or from an insurance company in order to start in practice, and who was faced with heavy family obligations. In the fight which lay ahead all of them must be prepared to run a financial risk, and quite rightly so, but it was necessary to consider those who, with an intense desire to be loyal to the Association, might be faced with commitments which would prevent them from giving a decision in accordance with their beliefs. A group or committee ought to be set up to consider this matter and to work out some rather longer term plan whereby these people could be assisted. It is possible that the banks or insurance companies concerned might see their way clear to allowing the men who had these loans to be in a position to line up with the rest of the profession in this fight?

Mr. A. M. A. Moore seconded, and said that all these considerations applied equally to young consultants. Dr. Cockshut, while supporting the motion, thought there was no need to take a gloomy view, especially having in mind what had happened over the insurance capitation fee. Dr. F. Gray said that it was important to give these possible waverers the reassurance that in their special difficulties they would have the profession behind them. Dr. J. A. Brown said that it must not be supposed that if the fight came about there would be a big cessation of income. The people they had in mind would surely be able to make a sufficient income to carry them on with the help of the National Insurance Defence Trust. Dr. O. C. Carter hoped that prominence would be given to the fact that there was a very considerable sum available to meet cases of hardship, that the Emergency Guarantee Fund had very large guarantees from the National Insurance Defence Trust, from the British Medical Association, and from individual guarantors, and that the whole resources of the Association would be available if necessary in the circumstances outlined.

This statement was endorsed by a general expression of agreement by the Council, which then passed the resolution unanimously, and agreed to the setting up of a special committee whose reference would be generally to examine and report upon ways of assisting practitioners incurring hardship as a result of following the advice given to them by the Association in connexion with the proposed National Health Service.

Ex-Service Practitioners

Dr. Martin Brodie introduced the report of the Ex-Service Practitioners Committee, which had been considering two principal matters—namely, the position of the unemployed specialist and the position of the ex-Service practitioner who intended to enter general practice. On the position of the specialist Dr. Brodie said that the committee had had before it the scheme to which the Ministry of Health had given authority. Under this scheme the Ministry proposed, in the

case of fully qualified specialists able to take senior posts in hospitals, to invite local authorities and the larger voluntary hospitals to increase their establishments by creating additional whole-time posts wherever the volume of specialist work justified it. For practitioners who, though unable to prove intention to specialize before recruitment, had attained full specialist status in the Forces, the Ministry had agreed that, subject to approval by the deans and directors of postgraduate studies, Class III posts should be available under the Government's postgraduate scheme.

The committee had given further consideration to this whole problem and was addressing a communication to the deans and directors of postgraduate studies urging that the postgraduate scheme should be applied in a flexible manner in the case of ex-officers of graded status who contemplated taking up a specialty, and that such officers should be appointed to Class I posts and transferred, after a suitable period of training and a satisfactory report, to Class III posts. It was also putting to the Ministry and to the Director of the Postgraduate Federation a number of other points—for example, that further appointments should be made in municipal hospitals for Class I and Class III posts, and that the department should consider what practical help could be given to the ex-Service practitioner who was experiencing difficulty in obtaining employment between the date of his demobilization and his appointment to a Class I post.

Concerning the ex-Service doctor who intended to enter general practice, a discussion had taken place with representatives of the Ministry in the course of which the main difficulties had been stressed. These were shortage of houses, shortage of cars, and uncertainty about the compensation proposals as affecting both men approaching retirement and young practitioners who wanted an interpretation of the section of the Act regarding possible payment of compensation where financial hardship could be proved. Sir Arthur Rucker had given an undertaking that his department would look into the question of compensation being paid at or immediately subsequent to the appointed day to ex-Service practitioners who had incurred a heavy debt in the purchase of a practice. The anomalous position was duly pointed out whereby a practitioner might have to pay 4½% interest on a loan, whereas after the appointed day he was credited with a sum of money presumably sufficient to pay off the loan but not redeemable until death or retirement, on which sum he would be paid only 2½% interest.

The report was approved.

Organization

Dr. J. A. Pridham brought forward a report of the Organization Committee which was principally concerned with regional organization. A plan had already been proposed whereby the five Assistant Secretaries had each been apportioned one-fifth of the country so that the services of the central medical staff would be made available to all Divisions and Branches. The committee thought that this plan for regional visits by the Assistant Secretaries should be put into operation as a temporary measure, and that arrangements should now be made for the appointment of two additional Assistant Secretaries during the present session. Under this plan there would eventually be seven Assistant Secretaries available for part-time regional work, the share of their time devoted to regional work being approximately equal to the whole time of four officers. The entire problem is to be reviewed at the beginning of next session in the light of experience gained. It was pointed out that the inception of a National Health Service would raise problems within the structure of the Association, possibly necessitating a recasting of its central and local machinery.

Dr. Pridham also reported on the recent International Medical Conference held at B.M.A. House in London, and proposed that the Association accept membership of the World Medical Association, and that the payment of the provisional annual subscription (approximately £86) be approved. This was unanimously agreed to.

Dr. Pridham remarked that the International Conference was extraordinarily successful, thanks very largely to the outstanding chairmanship of the President of the Association (Sir Hugh Lett). Dr. Routley, the Canadian delegate, also contributed

in a marked degree to the success of the proceedings. He added that since the Conference the Americal Medical Association had joined the World Medical Association.

Retirement of the Editor

Dr. O. C. Carter, chairman of the Journal Committee, in bringing forward a report of his committee, said that it was with great regret he had to report the retirement, at the end of the present year, on his reaching the age-limit, of Dr. N. G. Horner, who had filled the editorial chair with great distinction since January, 1928, and before that had been, from 1917 onwards, Assistant Editor. Dr. Horner had conducted the *Journal* with great ability and success during an editorial reign which had included more than one very trying period. They all wished him good health and happiness in his retirement.

This expression was received with the most cordial acclamation by the whole Council.

Psychiatry and the Law

Dr. J. Thwaites (on behalf of Dr. Doris Odum, the chairman of the committee) brought forward a report from the Psychiatry and the Law Joint Committee, the membership of which is composed of representatives of the B.M.A. and of the Magistrates Association. The first subject dealt with was corporal punishment. The committee had previously brought forward resolutions in favour of the abolition of judicial corporal punishment both for juvenile delinquents and for adult offenders, but after some discussion the Joint Committee had been asked to bring up the matter again. It now reaffirmed these resolutions, and gave the text of its reconsideration of the subject. The form of the report was criticized by certain members, and in view of the importance of the subject, the controversy likely to arise out of it, and the lateness of the hour, it was agreed to defer further consideration to the next meeting of Council.

Another report brought forward by the Joint Committee on "The Unstable Adolescent Girl" was unanimously approved as a most excellent document, and it was agreed that it be forwarded to the appropriate Government departments for consideration, published in the *Journal*, and reprinted as a joint B.M.A. and Magistrates' Association publication, subject to the concurrence of the latter body.

The General Medical Council

Mr. Dickson Wright presented the report of a special committee of the Association which has been considering the disciplinary powers of the General Medical Council. He said that the committee had had before it the G.M.C.'s own draft Medical Bill and the proposals of the Defence Societies. There were 31 recommendations set out in the committee's report, many of them of a far-reaching character.

Dr. J. W. Bone considered that it would be very unfortunate if this report, without much more consideration, went forward to the Government as the Association's view. He thought it should be sent back to the committee to deal with points which admittedly they had not as yet taken up, and that if possible another conference should be held with representatives of the G.M.C. and of the Defence Societies. After some slight discussion it was agreed that this report should stand over and be considered, along with part of the report of the Psychiatry and the Law Committee and other held-over business, at an extra meeting of the Council on Dec. 11.

Other Committee Reports

Dr. Vaughan Jones presented a progress report by the Industrial Medicine Committee. He said that the committee was proposing to give immediate consideration to the question of the development of an industrial medical service. It was understood that the Minister of Labour had asked his advisory committee to prepare a practical scheme, and the B.M.A. had been invited to submit a memorandum.

Gen. R. W. D. Leslie, for the Naval and Military Committee, reported that a request had been made to the India Office to receive a deputation on the terms of compensation to be offered to officers in the I.M.S. consequent upon the constitutional changes in India. On the recommendation of the Dominions Committee the Colonial Office is to be asked again to consider the appointment of a representative of the Association on the

Colonial Advisory Medical Committee. It appeared that the Secretary of State had been under a misapprehension when this request was first made, supposing the concern of the Association to be primarily with terms and conditions of service, whereas the Association was in a position to offer constructive advice on matters of medical policy.

The Liaison Committee of the B.M.A. and the Royal College of Nursing reported that it had had a preliminary discussion on the status of the nursing profession, and hoped to report fully to the Council after its next meeting at which a memorandum of practical proposals would be submitted by the Royal College.

On the Scottish Committee report Dr. G. MacFeat stated that in view of the imminence of a National Health Service Act for Scotland a Public Health Subcommittee had been appointed, with suitable representation.

On the motion of Dr. Waterfield, chairman of the Central Ethical Committee, it was agreed to ask the British Dental Association to consider the advisability of an arrangement between its Law and Ethics Committee and the Central Ethical Committee whereby two representatives of each committee should attend meetings of the other when ethical matters of mutual interest were under discussion.

The reports of the Finance, Building, and Science Committees, which dealt with routine matters, were approved. On the report of the Office Committee it was agreed unanimously to recommend to the Representative Body that Dr. J. C. Matthews and Dr. H. W. Pooler be elected Vice-Presidents of the Association. On the Public Relations Committee Dr. W. D. Steel urged that there should be a scrutiny of all newspapers for inaccurate reports, which should be countered forthwith, and that an effort should be made to secure a representation of Association intelligence in local newspapers. Dr. Dain, the chairman of the committee, replied that for some time past the committee had been doing these very things though it was not always possible to scotch a misleading report.

The Film Committee reported that it had devoted three meetings to preliminary discussions and proposed to draw up a report on the use of visual aids in medical teaching.

The Chairman of Council reported that, in view of the urgency of the matter, he had appointed a special committee to prepare a memorandum of evidence, the submission of which had been invited, for the special committee set up by the Home Secretary to inquire into various matters of health, welfare, and safety at places of employment other than those regulated under the Factories and similar Acts.

An invitation to the Association to become a member of the new National Association for Mental Health presently to be incorporated was accepted, and Dr. R. G. Gordon was appointed as the Association's representative on the Council of that body.

THE DANISH MEDICAL ASSOCIATION

The accounts appearing from time to time of the activities of the Danish Medical Association in its weekly organ, *Ugeskrift for Læger*, show how varied are the claims made on it. There are however, times when a limit has to be put on such claims, as when for example, the secretariat of the Association is asked to play the part of a travel agency or a money exchange. Among the legitimate claims are those made by Branches of the Association seeking advice on ethical problems such as the limits within which members of the Association can work without impairing the dignity of the medical profession. What, a local Branch of the Association asked, was to be done with one of its members who had been fined 800 kroner (or 30 days) for having issued a wealth of prescriptions for alcohol without any definite medical indication for the need thereof? The advice given from headquarters was that the offender should be reprimanded and warned that in the event of a relapse he might find himself excluded.

Another problem referred to headquarters concerned a doctor who had been invited to act as a judge for an examination at a "beauty institute." Could he do so without prejudice to the ethical exercise of his profession? Headquarters replied that the statutes of the Danish Medical Association did not directly forbid judicial activities on the part of its members in the course of an examination in "beauty culture." Nevertheless, the Association would consider such co-operation on the part of its members as exceedingly unfitting for experience had shown that the next step to a doctor's acting as a judge at a beauty institute was the appearance of an advertisement to the effect that such and such a person had satisfactorily passed a medical examination in "beauty culture."

HEARD AT HEADQUARTERS

"Yes" or "No"

The organization of the plebiscite has meant another big effort by Headquarters staff, which by now, however, is inured to exceptional calls upon its energies. To address and place the eight enclosures in 58,000 envelopes is no small undertaking. The Council decided to accompany the forms by return postage, or because it supposed that any practitioner would regard his reply as not worth twopence-halfpenny but because it was anxious that no form should be put on one side and forgotten wing to a stamp not being immediately available. That decision, as a little arithmetic will show, cost the Association something like £600.

Time Lag

Dr. J. B. Cook, who is the new president of the Hunterian Society, delivered a learned and interesting address from the chair of that body on the subject of "Municipal Medicine." He was carefully non-controversial, keeping largely to history. Out some of those who followed him in discussion observed much self-denying ordinance. One of them pointed out the considerable time-lag which has always intervened between the discovery of a new remedy or method of prevention and its acceptance by the "authorities." He mentioned advances in the treatment of tuberculosis, the campaign against venereal diseases, the institution of antenatal care, and many other movements, some of which were begun by pioneers fifty years before the ideas came to be adopted by municipal medicine, though when they were adopted they were carried to a degree of efficiency beyond what was possible so long as they were in voluntary or private hands. "But what," asked one speaker, "is to happen when medicine becomes entirely 'municipalized'? With a total State service this outside voluntary pioneering stimulus will be damped down." The municipal hospitals had their critics and defenders in a lively debate.

Service Medical History Records

Doctors who act as medical referees to insurance companies have found lately that if they wish to have particulars of the service medical history of an applicant for life assurance the Ministry of Pensions refuses the information on the ground that it is confidential. This matter has been taken up by the Association with the Ministry, but the reply is that the Ministry is only a custodian of the documents for the Service Departments. Therefore the question was shifted to the War Office, and it was asked that such records should be available for the purposes of a life assurance proposal, as they are already to insurance practitioners for the purposes of treatment. The Army Council, however, with the concurrence of the Board of Admiralty and the Air Council, has replied that, while the medical particulars available in Service documents are given to the doctor who needs them for the purposes of treatment, they are not to be given for a different purpose—namely, insurance. "The considerations that many ex-Service men might consent to their medical history being given, and that the information would be carefully safeguarded, do not affect the [Army] Council's views that the interests of Service personnel generally, and of medical officers in the Service who have to report on them, would be adversely affected by any measure of disclosure of medical particulars for a purpose other than medical treatment."

SCOTLAND'S HEALTH SERVICE BILL

Full consultations with the local authority associations at all stages in the setting up of the service to be provided under the National Health Service (Scotland) Bill were promised by the Secretary of State for Scotland when he met representatives of the Convention of Royal Burghs, the Association of Counties and Cities, and the Association of County Councils in St. Andrew's House, Edinburgh, on Nov. 15. On Nov. 18 members of the medical profession met the Secretary of State, and in the afternoon he had discussions with representatives of the British Hospitals Association, who presented the views of the voluntary hospitals.

WHOLE-TIME NON-PROFESSORIAL MEDICAL TEACHERS, LABORATORY AND RESEARCH WORKERS GROUP

REPORT ON WORK OF GROUP COMMITTEE

The first meeting of the Group of Full-time Non-Professorial Medical Teachers, Laboratory and Research Workers was held at B.M.A. House, on March 25, 1938. The meeting decided to appoint an executive committee on a territorial basis, as follows:

Area	Members
London	2
Oxford and Cambridge	1
Manchester and Liverpool	1
Durham, Leeds, Sheffield	1
Birmingham, Bristol, Wales	1
Scotland and Northern Ireland	2

Dr. W. Susman was subsequently appointed chairman of the committee, and held this office until August, 1946.

The committee, empowered to conduct the business of the Group, is responsible for representing the interests of its members. Its findings are placed before the Consultants and Specialists Committee and through the latter before the Council and Representative Body. The Group Committee is represented on the Consultants and Specialists Committee and may also send a representative to attend meetings of other committees and Council when matters affecting the Group are being considered.

Membership of the Group

Membership of the Group is open to members of the British Medical Association engaged full-time as non-professional medical teachers, laboratory or research workers. All applications for membership of the Group are first considered by the Group Committee, and the membership now totals 119.

Matters of Interest considered by the Group Committee

The greater part of the committee's time has been taken up with the drafting of a revised scale of salaries for whole-time non-professional medical teachers, laboratory and research workers. The committee found that comparatively few of the posts of demonstrator or "assistant" carried a commencing salary of £300 a year, that few readerships or senior lectureships carried a commencing salary of £750 a year, and that the salaries of intermediate appointments were far from uniform even in one and the same university, and in many cases were considerably below the minimum considered appropriate.

Remuneration of Whole-time Non-professorial Medical Teachers, Laboratory and Research Workers

The committee has collected information both on present scales of salaries for whole-time non-professional medical teachers, laboratory and research workers, and on scales likely to be appropriate in the future, and will shortly be submitting the latter to a special subcommittee of the Consultants and Specialists Committee set up to consider the remuneration of consultants and specialists generally.

Miscellaneous Business

The question of superannuation and the disability of research workers in connexion with scientific grants were under consideration in 1938 and inquiry has been made regarding the extent to which educational allowances for children of non-professional medical teachers were available at the various universities and medical schools. In addition the provision of compensation for illness contracted in the carrying out of professional duties was discussed. The Group Committee recorded its opinion that it was desirable that the universities should bear a proportion of the expenses incurred in travelling to and from scientific meetings on not more than two occasions in the year.

The Group Committee has recently been re-elected as follows, and with a return to more normal conditions can look forward to an interesting session:

Dr. Georgiana M. Bonser, Leeds.
Dr. C. J. C. Britton, London.
Dr. J. Gough, Cardiff.
Dr. J. W. Howie, Aberdeen.
Dr. A. C. Lendrum, Glasgow.
Dr. W. R. M. Morton, Cambridge.
Dr. A. J. Rhodes, F.R.C.P.Ed., London.
1 vacancy.

It is intended to arrange a meeting of members of the Group on Jan. 2, 1947, at which an opportunity will be given to all

members to put forward suggestions and recommendations which they wish to be considered by the Group Committee.

Finally, the Group, if it is to be effective, must be as large and representative as possible. If you are a full-time non-professional medical teacher, laboratory or research worker and do not belong to the Group you are invited to complete the appended form and send it to the Secretary, B.M.A. House, Tavistock Square, London, W.C.1.

I wish to apply for membership of the Group of Full-time Non-Professorial Medical Teachers, Laboratory and Research Workers. I understand that the inclusion of any individual within the Group is at the discretion of the Group Committee subject to appeal to the Council of the Association. I am a member of the Association and am engaged full-time as a ^{* non-professional medical teacher.} laboratory or research worker.

Correspondence

The "Closed Shop"

SIR,—Recently I answered an advertisement in your columns for the post of full-time medical officer at a borough council. I received in reply an application form and the following notice. No covering letter was included. [Extract of notice:]

"(1) That trade union membership be a condition of employment of all persons continuing in or entering the service of the Council, and that present employees who are not members of a trade union be advised of this decision and given a reasonable time—i.e., by Nov. 1, 1946—in which to join a trade union.

(2) That each Chief Officer be instructed to report to the December meeting of the Establishment Committee upon the position in his department, and subsequently as the Establishment Committee may direct."

I will not comment upon the manner of reply but will confine my remarks to the contents of the notice. The full implication of the first paragraph must be obvious to all. This is that the medical officer will be controlled by a trade union, which will show, I imagine, scant respect for his profession. He will be one tool in the hand of the ruling power behind the Government.

Surely it is obvious to all that the curtains are now drawn and the set of the Government stage is plainly visible. This setting is, in my opinion, very terrifying and reminiscent of past events in other lands. I sometimes feel that there are not enough original thinkers left in the medical profession to form a unity that will break the regimentation and coercion that is threatening to engulf and destroy us.

I will end by suggesting that the B.M.A. should take an immediate and strong stand with regard to the first paragraph of the above notice, and that no medical journal should accept any advertisement originating from a Labour source without investigating first the conditions imposed.—I am, etc.,

F. R. ELLIS.

*. Note by the Secretary of the B.M.A.: A statement will shortly be made by the Association on the important problem raised by Dr. Ellis.

SIR.—It is to be hoped that the profession is considering the implications of the present "closed shop" campaign with reference to the new National Health Service. I have already heard of one group of nine applicants for an appointment being reduced to two who were members of a certain medico-political organization.—I am, etc.,

London, W.11.

"NON-UNIONIST."

Medical Unemployment

SIR,—I would like to draw attention to one aspect of medical unemployment which has received little publicity. I refer to that existing among ex-Service holders of the D.P.H. Certificate appears to be remarkably keen for even the unattractive humbler posts, so miserably paid. No doubt this is in accordance with the general situation, but my grievance is the complete absence of any expressed preference for ex-Service doctors, and the conspicuous absence of any space for details of Service experience in the application forms provided, apparently obtains in all local authority appointments and surprisingly, in departments of central government, as can be seen in the many pages of advertisements appearing each week in the *Journal*. All honour to the Government of Northern Ireland, the outstanding exception! But I fear will be inundated with applications on that very account.

I can hear the question being asked, "Why should Servicemen get preference?" Which is quite reasonable—but national service should not be the positive handicap which it appears to be at present. We have heard that there was to be "a gentleman's agreement" to ignore the 5 or 6 years war service when it came to job hunting. What a conceit—as if in effect to say, "We know you've been in the 5 or 6 years, old chap, but we won't hold it against you." At my own experience it has not even worked out like that. I have had the impression strengthened that war service actually a deterrent to getting a job.

I have yet to meet a doctor (other than a holder of a D.P.H.) who does not think the D.P.H. "a very good thing to have these days." But I would warn aspirants to think before spending the time and the money. So far it has had the effect of diverting me from the serious business of finding a place in general practice. I have been sorry to see the waning of the correspondence on this subject. I do believe that the problem has been solved. Perhaps, like the despairing victims are busy casting round for reasons to prospects outside medicine.

To prevent repercussions I ask leave to sign myself

Aberdeen.

ANOTHER OF THE UNEMPLOYED

Remuneration of Doctors' Wives

SIR,—The point has been raised before but should again be considered. I feel that whatever scheme is operated in the future the proper remuneration of the doctor's wife should be considered. At the present moment I believe one may pay an annual allowance of about £90, but in my view, though it gives some tax relief, an adequate salary for services rendered—receptionist, clerk, telephonist, etc.—would be more in the region of £300 a year. I suggest, therefore, that this be a matter for negotiation—if negotiation is to continue with the Minister. Presumably he is ideologically opposed to any form of sweated labour? Or should I write Labour?—I am,

Colchester.

G. C. PETHE

H.M. Forces Appointments

ARMY

Major-Gen. Sir E. W. C. Bradfield, K.C.I.E., O.B.E., has been granted the honorary rank of Lieut.-Gen.

Col. D. G. Cheyne, C.B.E., M.C., having reached the age of retirement is retained on the Active List supernumerary.

Lieut.-Col. G. D. Gripper, from R.A.M.C., to be Col.

ROYAL ARMY MEDICAL CORPS

Lieut.-Col. J. H. C. Walker to be Col.

Lieut.-Cols. L. M. Rowlette, D.S.O., M.C., C. F. Anthonisz, J. McFadden have retired on retired pay and have been granted the honorary rank of Col.

Lieut.-Col. J. M. MacKenzie, C.B.E., M.C., is Seconded Service.

Lieut.-Col. H. A. Ferguson and Major (War Subs. Lieut.-Col.) A. D. Bourne have retired, receiving gratuities, and have been granted the honorary rank of Col.

Lieut.-Col. R. M. Davies, retired, re-employed, has reverted to retired pay, on account of disability.

Major W. D. C. Kelly, D.S.O., M.C., has been restored to rank of Col. on ceasing to be re-employed.

Majors (War Subs. Lieut.-Cols.) W. A. Y. Knight and C. S. Gross be Lieut.-Cols.

Majors T. M. Corcoran, J. B. George, D. P. F. Mulvany, and J. Curran to be Lieut.-Cols.

The initials of Major M. F. Kelleher, M.C., are as now described but as stated in a *Supplement to the London Gazette* dated April 26.

Major C. J. Blaikie, retired pay, re-employed, has been restored the rank of Lieut.-Col., on ceasing to be re-employed, and has been granted the honorary rank of Col.

Major C. McQueen has ceased to be employed on account of disability, has reverted to retired pay, and has been restored to the rank of Lieut.-Col.

War Subs. Lieut.-Col J. B. M. Milne, O.B.E., to be Major.

Capt. (War Subs. Major) M. Kosloff has retired and has been granted the honorary rank of Lieut.-Col.

Short Service Commission.—War Subs. Major J. C. A. Marchand is retired on account of disability and has been granted the honorary rank of Lieut.-Col.

Capt. (War Subs. Lieut.-Col.) J. B. Bunting to be Major.

War Subs. Majors R. G. Davies and A. L. J. Webb to be Majors.

Capt. (War Subs. Major) F. B. Bagshaw to be Major.

Capt. H. J. Anderson, E. D. H. Williams, J. A. Allen, R. D. H. G. L. Humphreys, F. J. Ingham, A. B. Fountain, G. E. Gray, and W. J. A. Craig to be Majors.

Capt. D. M. Macdonald has retired on account of disability, and has been granted the honorary rank of Major.

Short Service Commissions.—War Subs. Major D. W. Davies, from A.M.C., T.A., to be Lieut., and to be Capt. Capt. (War Subs. Major) D. W. Davies has been appointed to a permanent commission.

War Subs. Capt. D. Gill, H. J. Elverson, O. G. Jones, G. M. Ewan, and W. S. Rhodes, from R.A.M.C., Emergency Commissions, to be Lieuts., and to be Capt. Lieuts. (War Subs. Capt.) I. F. Fraser and C. E. Perry, from A.M.C., Emergency Commissions, to be Capt. Lieuts.

War Subs. Capt. I. M. Grant, from R.A.M.C., T.A., to be Lieut. and to be Capt.

War Subs. Capt. J. L. Huggan and W. P. Lee, from R.A.M.C., Emergency Commissions, to be Capt. Lieuts.

Capt. E. D. H. Williams, E. M. Ensor and A. J. Moss-Blundell have been appointed to permanent commissions.

Capt. D. E. S. Steele, from R.A.M.C. (Regular Short Service Commission), has been granted a short service (specialist) commission the rank of Capt.

REGULAR ARMY RESERVE OF OFFICERS

Col. C. M. Finny, O.B.E., late R.A.M.C., has been restored to the rank of Major-Gen. on ceasing to be employed.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Major R. Pollok has relinquished his commission on account of disability and has been granted the honorary rank of Major.

Capt. C. J. Mill-Irving, M.C., has relinquished his commission on account of disability and has been granted the honorary rank of Major.

Lieut. (War Subs. Capt.) J. P. P. Mackey to be Capt.

Senior Training Corps.—Lieut. A. H. Cruickshank, supernumerary for service with Aberdeen University Senior Training Corps (Med. Unit), has resigned his commission.

Lieuts. J. W. Chambers and A. Slessor, supernumerary for service with Glasgow University Senior Training Corps (Med. Unit), have resigned their commissions.

Major A. H. M. Eaton, supernumerary for service with Queen's University, Belfast, Senior Training Corps (Med. Unit).

Lieut. J. R. Wheeler, supernumerary for service with Queen's University, Belfast, Senior Training Corps (Med. Unit), has resigned his commission.

Lieut. J. A. Barclay, supernumerary for service with Birmingham University, Senior Training Corps (Med. Unit), has resigned his commission.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Subs. Lieut.-Cols. R. C. Speirs, R. Walkingshaw, M.C., and M. P. Campbell have relinquished their commissions and have been granted the honorary rank of Col.

Major J. N. P. Moore has resigned his commission.

War Subs. Major D. W. C. Gawne has relinquished his commission on reversion to the Southern Rhodesian Forces.

War Subs. Majors J. B. Arthur and A. Bigham have relinquished their commissions on account of disability and have been granted the honorary rank of Lieut.-Col.

War Subs. Majors G. King and J. C. Busby have relinquished their commissions and have been granted the honorary rank of Lieut.-Col.

War Subs. Capt. W. A. Elliott and H. D. Johnson have relinquished their commissions on account of disability and have been granted the honorary rank of Major.

War Subs. Capt. H. W. Webb, R. W. C. Kelly, A. L. Dunlop, A. Gellert, F. B. Notley, G. A. Williams, O. N. Ransford, and J. S. Sergeant have relinquished their commissions and have been granted the honorary rank of Major.

War Subs. Capt. S. Bayne, L. L. Bromley, G. R. Williams, W. L. Cooper, C. C. Ross, J. H. Maughan, J. A. Sykes, and D. F. G.

Moir have relinquished their commissions on account of disability and have been granted the honorary rank of Capt.

War Subs. Capt. D. S. Gibbs, R. Nicklin, P. H. D. Stone, and M. Makin have relinquished their commissions and have been granted the honorary rank of Capt.

War Subs. Capt. H. Polak, H. Fugs, R. F. H. Hinrichsen, G. H. Goldstucker, V. Dennis, and A. S. Manugian have relinquished their commissions.

Lieuts. R. Mendick and A. C. Arthur have relinquished their commissions on account of disability and have been granted the honorary rank of Lieut.

Specialist Short Service Commissions.—To be Lieuts.: J. M. Pullan, A. Brown, A. J. Heriot, J. L. Penistan, J. A. Rich, L. J. Wolfson, C. F. Chapple, G. D. Owen, N. H. Ashton, F. Post, W. J. L. Francis, T. M. J. d'Offay, W. M. Van Essen, J. Y. D. Wageham, P. Pau, F. S. Airey, I. Lopertas, A. B. McGrigor, A. C. Cunliffe, J. M. Mallett, N. Moulson, R. P. Parker, R. W. Wyse, R. R. Henderson, and E. E. O'Malley.

To be Lieuts.: C. F. Chapple, L. H. Tan, J. C. Busby, G. S. Andrew, R. A. Drury, F. Houston, O. D. Cuthbert, J. M. Park, R. C. B. Arthur, J. B. Brooks, M. Brown, E. S. Clarke, G. R. Cottrell, N. K. Crooke, L. F. G. Cruickshank, L. K. Dawson, R. B. Fitzgerald, A. H. Fraser, E. B. Gethen-Smith, W. T. Harrett, V. F. Harrison, P. W. Harvey, H. E. S. Pearson, C. B. S. Schofield, R. R. Stevenson, C. M. Taylor, D. M. Williams, J. Bauer, J. Armstrong, E. F. Riley, D. C. V. Stewart, and A. B. Wood.

War Subs. Lieut. W. F. Wille, from R.A.M.C., Non-medical Section, T.A. General List, to be Lieut.

ROYAL AIR FORCE

RESERVE OF AIR FORCE OFFICERS

Squad.-Ldr. R. F. Courtin, M.B.E., has resigned his commission, retaining the rank of Wing Cmdr.

Association Notices

GROUP OF ANAESTHETISTS OF THE B.M.A.

The newly formed Group of Anaesthetists of the British Medical Association held its first meeting at B.M.A. House on Nov. 1. There were present:

R. E. Angel, J. H. Attwood, T. H. Baillie, B. N. P. Bannatyne, Freda B. Bannister, V. T. Baxter, R. Binning, F. H. Blackburn, W. M. Brown, J. D. Buxton, S. Carden, Aileen M. Chesier, W. F. Chesters, S. Coffin, R. W. Cope, E. S. Curtis, H. W. Lofus Dale, M. H. A. Davison, A. De Freitas, O. P. Dinick, D. Divine, H. B. Dodwell, A. G. Donald, R. Erskine-Grav, H. W. Featherstone, D. K. Fisher, A. C. Forrester, Hilda M. Garry, Edith Gilchrist, J. Gillies, H. Girling, E. G. Godwin, V. A. Goldman, W. B. Gough, Marion Green, F. R. Gusterson, A. G. J. Harris, Beryl L. Harrison, J. K. Hasler, J. S. Hawes, P. J. Halliwell, G. R. Hopper, D. C. Howard, A. R. Hunter, Ronald Jarman, B. Johnson, H. Kahlenberg, G. S. A. Knowles, R. C. Lawrence, E. L. Littler, D. Lloyd-Davies, W. A. Low, B. G. B. Lucas, Florence M. McClelland, Dorothy McNair, A. D. Marston, J. Mennell, J. Montgomerie, F. I. R. Moore, T. T. P. Murphy, B. L. S. Nurtag, H. Newton-Andrews, A. Offenheim, G. Organe, G. F. Pantion, H. H. Pinkerton, R. E. Pleasance, Dorothy S. Price, W. K. Rae, S. G. Ransom, Frances A. Redhead, Mary M. Richmond, F. W. Roberts, K. M. Ross, W. H. Scriven, G. F. R. Smith, R. J. M. Steven, S. V. Strong, K. S. Thom, F. L. Turner, Daphne Veale, K. Mary Watson, S. Walters, G. L. Way, Marion E. Williams, Helen M. Wood, F. G. Wood-Smith, A. D. Woolf, Edith Winternitz, H. R. Youngman.

The Secretary opened the meeting by extending, on behalf of the Council of the Association, a warm welcome to all those present. Dr. A. D. Marston was appointed chairman of the meeting.

The meeting decided to recommend to the Council of the Association that the constitution of the Group Committee should be ten members directly elected on a territorial basis by members of the Group in the following regions:

	Members of Committee elected by members of the group in the regions
London	3
Provinces	5
Scotland	1
N. Ireland	1

together with a nominee of the Council of the Association of Anaesthetists of Great Britain and Ireland and a nominee of the Council of the Section of Anaesthetics of the Royal Society of Medicine.

It was reported to the meeting that 424 applications for membership had been received.

Dr. A. D. Marston was appointed the representative of the Group on the Consultants and Specialists Committee until such time as the Group Committee assumed office and appointed one of its members.

A number of important matters await consideration by the Group Committee, including the status of anaesthetists in the proposed National Health Service and safety in modern anaesthesia.

The Council has since approved the constitution of the Group Committee and arrangements are now being made for the election of members to the committee.

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows: an Ernest Hart Memorial Scholarship, of the value of £200, a Walter Dixon Scholarship of the value of £200 and four Research Scholarships, each of the value of £150. These Scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State Medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession. Each Scholarship is tenable for nine months, commencing on Feb. 1, 1947. A Scholar may be re-appointed for not more than two additional terms. A Scholar is not necessarily required to devote the whole of his or her time to the work of the research, but may hold a junior appointment at a university, medical school, or hospital, provided the duties of such appointments do not interfere with his or her work as a Scholar.

Conditions of Award, Applications

Applications for Scholarships must be made not later than Saturday, Dec. 28, 1946, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association B.M.A. House, Tavistock Square, London, W.C.1. Applicants are required to furnish the names of three referees who are competent to speak as to their capacity for the research contemplated.

Diary of Central Meetings

DECEMBER

5 Thurs. Publishing Subcommittee, 11 a.m.

Branch and Division Meetings to be Held

EAST HERTS DIVISION.—At County Hospital, Hertford, Thursday, Nov. 28, 8.30 p.m. Dr. H. Guy Dain, Chairman of B.M.A. Council: The National Health Service. All medical practitioners in the area of the Division are invited.

SALISBURY DIVISION.—At Cathedral Hotel, Salisbury, Wednesday, Nov. 27, 7.30 p.m., Dinner 8.30 p.m., Dr. G. D. Kersley: Differential Diagnosis and Treatment of Rheumatoid Arthritis: Illustrated by lantern slides. All medical practitioners in the area of the Division are invited.

SWANSEA DIVISION.—At General Hospital, Swansea, Thursday, Nov. 28, 8.15 p.m. Address by Mr. A. L. D'Abreu: Wales and Thoracic Surgery.

Meetings of Branches and Divisions**COVENTRY DIVISION**

An ordinary general meeting of the Division was held in the Board Room of the Coventry and Warwickshire Hospital on Nov. 5. Dr. E. C. K. Kenderdine was in the chair, more than thirty members of the Division were present. The chairman introduced Dr. Douglas Guthrie—the eminent medical historian and librarian of the Royal College of Surgeons of Edinburgh, who was to deliver the annual B.M.A. lecture.

Dr. Guthrie's subject was "The Patient in Medical History," and he took as his text a quotation from Wilfred Trotter commenting on the heroism of the first man to submit to surgical treatment for cerebral tumour. First, slides showing evidence of disease in the pre-Christian era were shown, and as later centuries came into view Dr. Guthrie dealt with known patients such as Alexis St. Martin and James Phipps. He also reviewed the work of medical men themselves patients, and he spoke of inventions of importance to medicine made by laymen—instancing the laryngoscope. Dr. Guthrie pointed out that in any advance in medical treatment the patient must be considered a partner—sometimes active, sometimes passive—and he deplored the habit of patients being known by numbers or initials. He emphasized that the tendency to ignore the patient and treat his disease must be discouraged, and he felt that there was a danger of so much attention being paid to the chemistry of the patient that he as an individual might be forgotten, and he reminded his audience that the doctor could learn a very great deal from an intelligent patient.

An enthusiastic vote of thanks, proposed by Dr. H. N. Gregg, G.M., and seconded by Dr. Gloria Richards, was accorded to Dr. Guthrie. In his reply Dr. Guthrie laid stress on the point that whatever happened to medical practice in the future the doctor-patient relationship must be preserved.

WEEKLY POSTGRADUATE DIARY

BLACKPOOL: VICTORIA HOSPITAL.—Thurs., 8 p.m. Dr. Yates: Antibiotics and Antiseptics in the Control of Infection.

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Edinburgh Royal Infirmary, Tues., 5 p.m. Mr. D. M. Douglas: Experimental Approach to Surgery.

LONDON SCHOOL OF DERMATOLOGY. 5, Lisle Street, Leicester Square, W.C.—Thurs., 5 p.m. Dr. H. Gordon: Limitations of X-ray Therapy in Dermatology. Thurs., 5 p.m. Dr. A. D. Porter, Vitamin A in Dermatology.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn F.W.C.—Thurs., 5 p.m. Erasmus Wilson Demonstration by R. W. Raven: Diseases of the Pharynx and Oesophagus.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS, 58, C. Ann Street, W.—Fri., 5 p.m. Dr. J. F. Loutit: The R. Facor.

ROYAL SOCIETY OF MEDICINE

Section of Odontology.—Mon., 5.30 p.m. Mr. D. Greer Wa Severc infections of the mandible. Prof. M. A. Rushon: Reg osteitis fibrosa affecting the facial bones: 2 cases.

Section of Medicine.—Tues., 5 p.m. Discussion: Birth con some medical and legal aspects. Openers: Dr. E. B. Ford, Aleck Bourne, Dr. Kenneth McFadyean, and Mr. Justice Humph.

Section of Urology.—Thurs., 8 p.m. Presidential address: Mr. R. H. O. B. Robinson: Some problems of renal lithiasis.

Section of Endocrinology.—Fri., 5.45 p.m. (Cases at 5 p.m.)

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Sq W.—Mon., 8.30 p.m. Discussion: Diagnosis and treatment Aural Vertigo. To be introduced by Mr. W. M. Mollison Dr. Philip Cloake.

SOCIALIST MEDICAL ASSOCIATION.—At Denison House, 296, Vau Bridge Road, S.W., Thurs., 7.30 p.m. Dr. F. Avery Jo Social Aspects of Peptic Ulcer.

SOCIETY OF CHEMICAL INDUSTRY: Food Group (Microbiolo Panc).—At Chemical Society, Burlington House, Piccadilly, Wed., 6.15 p.m. Mr. H. C. S. De Whalley and Miss M. Scarr: Micro-organisms in Raw and Refined Sugar and Intermediate Products.

APPOINTMENTS

BANNISTER, Freda B., M.D., D.A., Honorary Anaesthetist, Chester Infirmary.

CHIEFSEA HOSPITAL FOR WOMEN.—Director of Pathology, Magnus H M.D. Genito-urinary Surgeon, Terence Millin, F.R.C.S.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.—Orthopaedic Fracture Surgeon, J. C. R. Hindenach, F.R.C.S. Honorary Physiotherapist, John Enzer, M.R.C.S., L.R.C.P.

HERVEY, W. A., F.R.C.S. Ed., Honorary Oto-Rhino-Laryngologist, (Maly's Hospital for the East End, Stratford, E.)

LANELAND DISTRICT MEDICAL SERVICE.—Consulting Physician, I. Swick, M.D., M.R.C.P. Second Surgeon, J. F. Dignam, M.B., B.Ch., F.R.

LONDON HOSPITAL, Whitechapel, E.—Assistant Surgeon to Aural Department, A. Bowen-Davies, M.B., F.R.C.S. Assistant Surgeon to The Department, Vernon C. Thompson, F.R.C.S. Assistant Surgeon to C poedle and Accident Department, O. J. Vaughan-Jackson, F.R.C.S. As Physician to the Hospital, Kenneth M. A. Perry, M.D., M.R.C.P.

PRESTON, J. R., M.B., Ch.D., D.P.H., Medical Officer of Health, Borough Sutton Coldfield.

RAFTERY, Lillian, M.R.C.S., L.R.C.P., M.R.C.O.G., M.M.S.A., Hon Visiting Gynaecologist, British Red Cross Society's Clinic for Rheumatism.

SMITH, A. G., M.D., F.R.C.S., medical referee for dermatological under the Workmen's Compensation Act, 1925, for county court district Norfolk and Suffolk (Circuits 32 and 33).

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or Extra words 3s. 6d. for each six or less. Payment should be forwarded the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

BINTCLIFFE.—On Nov. 8, 1946, at Birmingham, to the wife of E. W. Blat M.B.E., M.S., F.R.C.S., a son.

COATES.—On Nov. 13, 1946, at the Mornington Nursing Home, Bradford Margaret (née Gatenby), wife of J. C. Coates, F.R.C.S., a daughter.

EVANS.—On Nov. 10, 1946, at Nuffield House, Guy's Hospital, to Winifred wife of Dr. M. L. Hudson Evans, of Lewisham, a son—Timothy.

HATFIELD.—On Nov. 15, 1946, at Ongar House, Ongar, to Sylvia Hertford, wife of F. E. S. Hatfield, M.B., B.Chir., a daughter.

HOVENDEN.—On Nov. 9, 1946, to Mary (née Powell), wife of Dr. T. G. Geor Hoven, 99, Church Road, Barnes, S.W.13, a daughter.

MACFARLANE.—On Nov. 15, 1946, at the City of London Maternity Hospital Dorothy (née Griffin), wife of Dr. J. A. Macfarlane, a son.

MATTHEWS.—On Nov. 16, 1946, at the Wickham Nursing Home, Lewes Diana (née Sykes), wife of Philip Matthews, a daughter.

OWLES.—On Nov. 1, 1946, to Norah (née Ryan), wife of Wilfred Harri Owles, D.M., M.R.C.P., of 7, South Parade, Llandudno, a son.

PEPLER.—On Nov. 14, 1946, at the South London Hospital for Women, S.V. to Cecily, M.B., B.S. (née Stuart-Bunning), wife of D. S. Pepler, of Clare Court, W.C.1, a son.

PRICHARD.—On Oct. 9, 1946, at the London Hospital, to Joan (née Webb) wife of John Stobo Prichard, M.C., 2, Hanway Place, W.1, a daughter.

WAGGOTT.—On Oct. 26, 1946, to Winifred (née Cunningham), M.B., B.Ch. wife of John Waggon, 40, Barnsdale Avenue, Thingwall, Cheshire, a son.

WHILES.—On Nov. 2, 1946, at 57, Burton Road, Derby, to Marjorie, wife Dr. W. H. Whiles, a daughter—Della Sylvia.

DEATH

RINGROSE.—On Nov. 7, 1946, at the Brotherton Wing, Leeds, Doris M Ringrose (née Hopps), M.B., Ch.B.Ed., D.P.H., of Westfield, Arcliffe Rd Leeds, 6, aged 46.

LONDON SATURDAY NOVEMBER 30 1946

CHEMOTHERAPY OF TUBERCULOSIS

RESEARCH DURING THE PAST 100 YEARS*

BY

P. D'ARCY HART, M.D., F.R.C.P.

Scientific Staff, Medical Research Council

PART I

Viewed historically, the conception of treatment in tuberculosis has been as complex and as changing as in any branch of medicine. Emphasis on it as a social disease, a hereditary stigma, a contagion, an inflammation, or a bacterial infection has determined the approach to treatment and prevention. In the present lecture I shall attempt to trace the historical development of the chemotherapeutic aspect of tuberculosis treatment, so that the physician, more particularly the non-specialist, may be helped to see in perspective the successes which, if not already in the foreground of the future, are perhaps no farther away than its middle distance. I shall aim to present this development in relation, on the one hand, to the tremendous advances in general chemotherapy, and, on the other, to the advances in the broad knowledge of tuberculosis and of its management and treatment; and I shall attempt to weave into the complex historical pattern the development of the use of antibiotic substances.

First, I must make clear how I propose to use the term "chemotherapy." Most revolutionary concepts are not static, and chemotherapy in the sense of Ehrlich, who first coined the word, is no exception. Conceived by him as a science which "treats of the action and mechanism of the effects of chemical substances upon cells, and especially of drugs upon disease-producing organisms" (see Kolmer, 1926), it has been restricted by some to artificially produced chemicals and expanded by others so as to include the pharmacotherapy of non-infective disease. All agree, however, that chemotherapy is to be differentiated from therapy by means of immune bodies or such microbial products as tuberculin, and that it excludes the chemical treatment of symptoms. I propose to follow Galdston (1940) and keep in mind the *objective* of chemotherapy given by one worker: "to destroy the parasites in the body of the host, or at least so to injure them that they will prove vulnerable to the host's own defensive powers," taking this definition to cover bacteriostatic as well as bactericidal action, and to imply the proviso of relative harmlessness to the host. I shall include, therefore, consideration of antimicrobial agents that are inorganic substances, that are purely synthetic organic compounds, and that are organic compounds obtained from natural or biological sources—e.g., those products of microbial origin now known as antibiotics, even though relatively few of these last have been isolated, purified, and characterized, and fewer still fully understood structurally. Divisions are rather artificial here, for what is obtained from biological sources to-day may be synthesized in the chemical laboratory to-morrow, and series of related compounds may be made the week after. Too precise a definition of chemotherapy is unwise, for, as originally visualized by Ehrlich in the strict sense, it involves complete internal disinfection in the living body with one or two doses; but Ehrlich himself allowed this interpretation to be widened as a result of experience. Again, Ehrlich undoubtedly conceived throughout his life the effect of chemotherapeutic agents as being produced primarily by direct and specific action upon the invading organisms—though the host's tissues might oxidize, reduce,

or otherwise convert an inactive drug to an active form. Yet there are instances where the action has been presumed to be wholly indirect—viz., stimulatory to the natural defensive mechanisms of the body (reticulo-endothelial system, etc.); such instances are properly regarded as examples of chemotherapy, and one of them—gold therapy—has been prominent in tuberculosis. Nevertheless it is true to say that the most successful recent efforts at specific chemical treatment can be explained on the basis of primary direct action of the agent on the micro-organisms.

The hundred years covered by the present review will, for convenience of discussion, be divided into four periods: 1850–80, 1880–1910, 1910–35, and 1935–46. The reasons determining these arbitrary divisions will be evident from Table I.

TABLE I

1850–1880
Pre-chemotherapeutic period—the background (A few traditional specifics of value in infective diseases—e.g., cinchona for malaria, mercury for syphilis)
1880–1910
Tentative period of chemotherapy (1880–1900) Period of first successes with synthetic substances (trypan red, salvarsan, etc.) in protozoal and spirochaetal infections (1900–10)
in tuberculosis
1910–1935
mental tuberculosis negative or inconclusive Gold therapy in clinical tuberculosis flourished (1925–35)
1935–1946
First success with synthetic drug (sulphanilamide) in systemic bacterial (streptococcal) infection in man (1935)
infection in man (1940–41) Streptomycin in experimental and clinical tuberculosis (1945–6)

1850–1880

The period 1850–80 was remarkable because the first foundations of modern chemotherapy were being rapidly laid, although success in this new branch of science, as a result of purposeful experiment and synthetic chemical search, was to come only later. Indeed, as Dale (1923, 1943) points out, there were few drugs of that time which, in the light of present knowledge, had remedial value due to action on the infective agents responsible for the diseases in which they were used—mercurials and iodides for syphilis, cinchona and quinine for malaria, and ipecacuanha for (amoebic) dysentery, to which we should probably add chaulmoogra oil for leprosy; and these remedies—triumphs of empiricism—antedated by some hundreds of years the discovery of the parasitic causes of their

* The Mitchell Lecture, delivered at the Royal College of Physicians, London, on July 9, 1946.

† An antibiotic substance may be defined shortly as a chemical substance produced by a micro-organism and found to be inhibitory to the growth or activity of other species of micro-organism (see also Waksman, 1945; Oxford, 1945).

respective diseases, and, in the cases of the biological products cinchona, ipecacuanha, and chaulmoogra, the elucidation of their active components.

In this pre-chemotherapeutic era we have the background of our subject. The most relevant of the many and exciting developments in science may be enumerated.

1. A phenomenal expansion of synthetic organic chemistry was accompanying the rise of the synthetic coal-tar dyestuffs industry. (This development was most prominent in Germany, due to the stimulus of economic demands and the lack of available natural products: yet it was an Englishman, Sir W. H. Perkin, who in 1856 prepared the first aniline dye (see Clegg, 1938).)

2. The science of human microbiology was being founded by the proof that micro-organisms could be factors in the causation and transmission of infectious diseases. Human diseases in which this was demonstrated included anthrax, relapsing fever, leprosy, gonorrhoea, and typhoid fever—but not yet tuberculosis. Pasteur and Koch were, of course, two of the giants in this field.

3. Pharmacology was ceasing to be a purely empirical subject, with the effects of drugs judged only at the bedside; and the advances both in synthetic organic chemistry and in physiology led to the union of these into an experimental science, and so to the study of the action of drugs on abnormal and artificially diseased animals—i.e., experimental pathology.

4. The selective staining properties of newly synthesized aniline dyes were being used by Weigert, Koch, and others.

5. Knowledge of local antiseptics was arising through the work of Lister and others; this advance, with phenol as starting-point in 1867, again illustrated how the influence of the distillation products of coal tar permeated the developments of this epoch.

In this pre-chemotherapeutic period, too, even the use of antibiotic substances in medicine was foreshadowed, for microbial antagonisms were first described in 1877 by Pasteur and Joubert, who had observed that the growth of anthrax bacilli *in vitro*, and the development of the disease *in vivo*, could be inhibited by certain air-borne micro-organisms; and these authors suggested that such antagonisms between different species might eventually have therapeutic applications.

As regards the advancing knowledge of tuberculosis, this period includes what Pagel (1927) has called the era of definite morphological investigation, arising out of Laennec's work and leading immediately into the period of experimental pathology and of the bacteriological study of experimental infections; thus we can see a thread running from Virchow's contributions to cellular pathology (1858), through Villemin's proof in 1865 of the specificity and transmissibility of tuberculosis, to Koch's discovery of the causative parasite in 1882. In the therapeutic field the principal measures recommended at this time were rest, sometimes tempered with exercise, and plentiful diet, often to the point of overfeeding, where the patient could afford it. The Brompton Hospital had been founded in 1848 and a sanatorium was started in Germany in 1859, but it was not till the end of the century that these methods began to be generally accepted; while fresh-air treatment was still a novelty to many and the rationale of isolation was disputed.

Among these general measures of treatment drugs found their place merely as one more weapon in the physician's armoury, and one which, perhaps wisely, many regarded as too blunt to use. There were, however, many others of whom Wells and Long (1932, p. 194) have written: "It was a time when a drug was seldom dropped, although it was a routine procedure to add one." Among the drugs there were quite an array which were commonly believed to strike at the root causes of tuberculosis and not merely at its symptoms—even though the bacillus was yet to be discovered—and their administration therefore deserves to be considered as an effort at empirical chemotherapy. These drugs were based largely on the traditions of the past, and showed little evidence of the impact of current advances in understanding of the pathology of tuberculosis. A patient of this time might have been treated with one or more of the following popular drugs in this class: (1) inorganic arsenical compounds, traditional for phthisis since antiquity (Hippocrates, Pliny); (2) tannin, an ingredient of anti-phthysical medicaments known to Avicenna in the 11th century; (3) cod-liver oil in very large doses, this product having been prescribed for consumption in 1774 by Thomas Percival, but having probably been in use among fisherfolk much earlier; (4) iodine or iodides, which, in the form of sea-

weed, had been recommended for scrofula by the Salerno School in the 11th and 12th centuries; (5) mercury and gold, the use of both of which for phthisis and for scrofulous glandular swellings, as well as for syphilis, dates from the time of Paracelsus and Fracastorius, early in the 16th century; and (6) creosote, which had originated more recently, around 1830. In addition to these drugs of international popularity there were countless supposed specifics of indigenous vegetable origin in various parts of the world—e.g., garlic in the Ayurvedic and Unani systems of medicine.

Clearly the controlled experimental search for chemotherapeutic agents in tuberculosis had not yet begun. Moreover, unlike the use of the traditional drugs—ipecacuanha, cinchona, and mercury—in protozoal and spirochaetal diseases, subsequent experimental work has failed so far to show a definite scientific basis for success of any of the early empirical "specific" remedies in tuberculosis, with the possible exception of the ingredients of cod-liver oil. However, we should keep an open mind on this matter.

1880-1910

The 30 years 1880-1910 saw the establishment of chemotherapy as a flourishing branch of medical science, but (apart from antiseptics through local application) the bacterial infections remained resistant, even though the micro-organisms causing most of them had been discovered by the end of this period.

In the first part of the period—viz., the last two decades of the century—the foundations of chemotherapy were being strengthened and many of its tools fashioned. The expanding production of synthetic coal-tar derivatives was creating a pharmaceutical science. Many new dyes were being synthesized, the bacteriostatic and bactericidal action of some of them demonstrated, and their power of manifesting micro-organisms, both in isolation and in the tissues, through selective staining (e.g., acid-fast stain) exploited. Knowledge of immunology was being rapidly accumulated. The scope of the new experimental pathology was widening, attention being directed to the infective causes that were being discovered in one disease after another, including tuberculosis, with the implication that the ultimate objective of treatment should be to cure through the eradication of the parasites by the specific action of immune bodies or antiseptic chemical substances, and not merely to assist Nature by alleviating symptoms. Furthermore, current reports of the antagonistic power of certain bacterial species against others were opening up the therapeutic potentialities of chemical substances synthesized by micro-organisms themselves, thus bringing the anticipations of Pasteur and Joubert nearer. Ehrlich, greatly influenced by this complex of developments, to which he was himself a contributor, was paving the way for his great work in the theory and practice of chemotherapy by forming his conception of selective and specific chemical affinities.

First Experiments in Chemotherapy

But laboratory chemotherapeutic experimentation had already started, and it is interesting for our purpose that what was probably the first such experiment in animals, using a definite chemical entity—i.e., an attempt to produce internal disinfection in a systemic infection—was made by Robert Koch in 1881, a year before he announced his discovery of the tubercle bacillus. Koch's experiment—a test of mercuric chloride, which was very active against anthrax bacilli in the test-tube, in anthrax-infected guinea-pigs—was not successful; nor were most of those experiments made subsequently in various protozoal and bacterial infections, including tuberculosis, by himself, Behring, Ehrlich, and other contemporary workers, using the older antiseptics and the newer synthetic dyes (methylene blue, however, was shown by Ehrlich and Guttman in 1891 to have some value in malarial infection). Indeed, by 1900 the number of chemical remedies that could be said on scientific evidence to deal directly with the causes of infective diseases had scarcely increased, and Dale (1943) describes this point as about the low-water mark of interest and confidence in the remedial value of drugs. The hope of bringing specific chemical substances into therapeutics, which the discovery of the aetiological role of micro-organisms

ad aroused, gave way to hopes based on specific immunotherapy, which had already produced such signal successes.

Yet, a few years later, the general outlook changed when the first great advance was made in the use of synthetic substances in chemotherapy; for in 1904 Ehrlich and Shiga produced virtually the first modern chemotherapeutic achievement—the rapid sterilization of an experimental trypanosomal infection (*T. equinum*) with a chemical synthesized for that particular purpose (trypan red). This was followed by further successes in the field of trypanosomal and spirochaetal infection, culminating in the first unequivocal application to human therapy—the use of salvarsan in syphilis in 1910 by Ehrlich and Hata. These successes were largely due to the systematic search by Ehrlich and his colleagues among synthetic coal-tar dyes and organic arsenicals in conjunction with test-tube and animal-infection tests. Here was the exploitation of the relation of the activity of therapeutic agents to their chemical structure, the “biological experimentation carefully co-ordinated with constructive chemical manipulation” (Lewis, 1917a) that is the very essence of therapy with synthetic chemicals. In contrast to these successes among the protozoa, in vivo laboratory experiments with synthetic substances in systemic bacterial infections during this decade were still negative or inconclusive, even though the substances used might be strongly inhibitory to bacterial growth in vitro.

A few years before Ehrlich and Shiga's historic success with a synthetic substance there was also a small but significant advance in the use of agents of microbial origin in chemotherapy when in 1889 Emmerich and Löw published their experiments on “pyocyanase” from *Ps. aeruginosa*. This work had been preceded, as Florey's (1945) fascinating review shows, by 20 years of scattered observations on the antagonistic relations of micro-organisms, following Pasteur and Joubert's original report, and including attempts to cure or protect animals infected with one species by administration of an antagonist. In these earlier *in vivo* experiments the antagonist had been provided mainly by whole bacterial cultures (living or sterilized), and, indeed, Cantani (1885), of Naples, claimed some success in human pulmonary tuberculosis by the insufflation of a particular saprophytic bacterial culture designated as “*Bact. termo*.” Now, however, apparently for the first time, a bacterial extract was found efficacious in experimental infection, for Emmerich and Löw reported that the injection of pyocyanase preparations could protect rabbits against anthrax; and cures of animals after infection were also noted with similar preparations. In the first decade of the century pyocyanase came into widespread clinical use in various infections, at first internally and later mainly by local application, but in spite of promising early results its use was eventually more or less abandoned, possibly with insufficient reason. During this period little further success was evidenced in microbial therapy in general, in either experimental or human infections; and I can find no record of the inhibition of growth of tubercle bacilli by the actual products of micro-organisms, even *in vitro*, before 1912.

Reversion to General Measures

What was happening during these 30 years in the field of human tuberculosis? The modern conception of immunity in this infection originated from Koch's experiments from 1891 onwards, and was added to by the results of necropsy series (Küss, Nageli, etc.) and of the diagnostic tuberculin test (Koch, Pirquet, Mantoux, etc.) in man; while the concrete turn given to the idea of contagiousness by knowledge of the transmission of the infecting micro-organism canalized preventive action into hygienic measures, sputum disinfection, etc. As regards treatment, after the initial high hopes of specific cure of tuberculosis by chemical agents which were raised by Koch's discovery of the bacillus, the change of emphasis from chemotherapy to immunotherapy (to which we have already drawn attention generally) became particularly evident, since Koch's production of old tuberculin in 1890, and his experiments on guinea-pigs with this and later similar products, caused his attention to be focused on tuberculin as a remedy in man; and in so doing he may have actually impeded therapeutic progress. Thus, Koch prefaced his description of tuberculin by naming a number of drugs (mercury salts, gold cyanide, etc.) that he

had found tuberculostatic in the test-tube but ineffective in animals; whereas he had found that tuberculin specifically and effectively acted on tuberculous tissue and in that way rendered the pathogenic bacteria harmless without injuring the body. Small wonder if the aim of chemotherapy, as applied to tuberculosis, received a setback and tuberculin therapy became the vogue. But when, after a tremendous wave of enthusiasm, confidence in specific treatment with the various tuberculins also began to wane in many quarters, and still no chemotherapeutic agent appeared to stand the test of controlled scientific experiment, many of the more critical physicians fell back on general measures to strengthen the patient's resistance—fresh air, rest, diet, etc. The still few but increasing number of sanatoria and special hospitals assisted in these measures, though ultimate results were so often disappointing. It may be recalled also that the first dispensary was opened by Robert Philip in 1887, and that in 1894, following isolated preliminary observations during the previous 70 years, Forlanini published his first series of results of artificial pneumothorax, though the latter treatment was not to become general for another 20 to 30 years.

Certain anti-phthisical drugs of the period, nevertheless, had a reputation for exerting either a specific direct action on the infecting organisms or an indirect effect through stimulation of host defences. These were substantially the same empirical and traditional remedies that we have listed as in use before the discovery of Koch's bacillus, though new reasons, often of tenuous nature, were offered for their supposed effects: salts of inorganic arsenic (and the recently introduced organic cacodylate), which not uncommonly resulted in liver damage; iannin, despite the fact that no inhibition was found in contemporary guinea-pig experiments; creosote and its derivatives, sometimes in enormous dosage, on the dubious rationale that a protective tissue reaction was promoted around the tubercle; cod-liver oil; iodides; and a revival of calcium administration (popular in antiquity, recommended in the 10th century by the Persian physician Mowaffak, in the form of powdered crayfish), on the assumption that it counteracted a supposed demineralization accompanying tuberculosis (see Piéry and Roshem, 1931). In addition to these standard remedies, salts of copper (A. and E. Luton in France) and gold (White (1891) and Gibbs and Shurly (1892) in the U.S.A.) were used sporadically; while a few clinicians attempted straightforward internal disinfection of their patients with antiseptics, despite lack of evidence of efficacy in non-toxic doses in animals. Thus, Dr. Vere Pearson recalls (1946) that Dr. Robert Maguire, a physician to St. Mary's and Brompton Hospitals around the turn of the century, gave a weak solution of formaldehyde intravenously, and that this, as well as a weak silver salt, had a vogue for a few years. I have omitted mention of the innumerable “consumption cures” of this period, whose patent lack of scientific basis did not get them far; and we are not concerned with symptomatic medication, for which, of course, a considerable number of drugs (including creosote) were used for apparently sound reasons.

1910-1935

So far, even taking into account the very suggestive experiments with pyocyanase, there had been no unequivocal demonstration of the chemotherapeutic sterilization of a general infection of bacterial origin in the animal living body. The cure of pneumococcal septicaemia in mice by Morgenroth and Levy in 1911, using “optochin,” a synthetic homologue of quinine, raised hopes in this direction, even though this experiment proved inapplicable to human therapy. But while, during the next 25 years, important new local antiseptics came to the fore in the control of bacterial wound infection and infected mucous membranes, particularly as a result of the first world war, attempts to effect cure of a systemic bacterial infection in man by internal chemotherapy were persistent failures. With the possible partial exceptions of new chaulmoogra derivatives in leprosy, and of sanocrysin and related compounds in tuberculosis (see later), mycobacterial infection shared in this failure. Ehrlich's (1914) warning, given at the International Medical Congress in London two years before his death, of the hard struggle that would be required for success in antibacterial chemotherapy—above all in tuberculosis—proved only too correct. Even local disinfection in tuberculosis was fraught with difficulty—witness the inconclusive

results with certain essential oils, such as "gommenol," in the pleural cavity.

Of the many chemicals—both new ones, and old ones in new forms—that were tested in the laboratory for anti-tuberculous activity during this period, some of the more important will be briefly discussed (for fuller surveys see Cummins, 1930; Wells and Long, 1932; Findlay, 1940).

Dyes—Cod-liver Oil—Chaulmoogra Oil

Various aniline dyes and chemical modifications thereof were investigated by Paul Lewis (1912-17), De Witt (1913-23), and others. Some—e.g., azo-dyes, members of the acridine series, and other basic dyes—showed selective inhibition of growth of the bacillus in the test-tube as compared with other bacterial species. Some, either alone or in a chemical combination with other agents such as metals, phenol, or iodine, penetrated and inhibited the bacilli *in vitro* and were able to penetrate the tubercles in the body; but while they might extend the life of infected guinea-pigs and rabbits and reduce the anatomical extent of the lesions—one of the most encouraging in this respect being methylene blue and its derivatives—they did not prevent or cure the experimental disease. None of these dyes found a place in internal medication in man.

Another group tested experimentally was crocetes and many allied preparations (e.g., thymol)—popular empirical remedies, as already stated. They were not found to be very highly bacteriostatic *in vitro*, and animal infection experiments failed to give evidence definite enough to justify their clinical use in tuberculosis on grounds of specific antibacterial action—any good results were more likely to be due to non-specific symptomatic effects.

Much experimental work was done during this period to find a rationale for the traditional use of cod-liver oil in human tuberculosis. On analogy with the apparent value of fatty acid fractions of chaulmoogra oil in leprosy, sodium morrhuate was investigated in the laboratory and was applied clinically in pulmonary tuberculosis, in lupus vulgaris, and in sarcoidosis, but the results were inconsistent (Cummins, 1925). Despite this, the presumed benefit of cod-liver oil was—and still is—attributed by some to a direct antibacterial action of component fatty acids. After the discovery of the fat-soluble vitamins, another hypothesis for the clinical benefit of cod-liver oil arose—namely, its A or D content. The few experiments on the effect of vitamin A deficiency in experimental tuberculosis were inconclusive (Steiner, Greene, and Kramer, 1937b), but the more commonly held possible explanation was the mobilizing action of vitamin D on calcium. In spite of the apparent association of calcification with healing, there was little clear direct experimental evidence in support of either calcium or vitamin D therapy (Mayer and Wells, 1923; Grant *et al.*, 1927, 1930; Steenkens and Baldwin, 1937; Steiner, Greene, and Kramer, 1937a); nevertheless, the value of these substances has been persistently maintained by many clinicians, and one hesitates to deny that the importance of calcium or phosphorus metabolism in tuberculosis treatment may yet be revealed—certainly the vitamin D factor in cod-liver oil requires re-examination in view of the recent clinical reports by Charpy and Dowling of regression of lupus after giving calciferol.

The possibilities in tuberculosis of the leprocidal chaulmoogra oil itself, and of its cyclic unsaturated fatty acid constituents—e.g., chaulmoogric and hydnocarpic acids (which had been isolated a little before the beginning of this period)—were also investigated; and structurally similar many-carboned fatty acids, containing rings or branched chains, were synthesized (see Robinson, 1940). Many of these natural and synthetic substances were tuberculostatic in the test-tube (Walker and Sweney, 1920; Stanley *et al.*, 1932). A number of them were tested in experimentally infected animals, and some prolongation of life and suppression of lesions claimed, but the matter remained in doubt; trials in human pulmonary tuberculosis also were inconclusive (see Wells and Long, 1932; Emmart, 1946). As will be noted later, interest in chaulmoogra derivatives and allied synthetic compounds, as well as in long-chain fatty acids in general, has been recently revived, and with more promise.

It is not possible to enumerate more than a few of the many other chemical substances that were investigated or reinvestigated *in vitro* or in experimental animal-infection during these 25 years. They include cinnamates, terpenes from essential oils (Courmont), and a variety of other organic compounds (e.g., see Kuroya, 1929; Meissner and Hesse, 1931; Hesse and Meissner, 1931); iodine and iodides; minerals such as coal (Cummins and Weatherall, 1931); and compounds of metals such as arsenic, mercury (De Witt, 1921), copper (Linden, 1912, 1920), and, above all, gold (Feldt, De Witt, Möllgaard), both in organic and in inorganic forms. The *in vitro* activity of some of these substances was high, but either they were toxic or the results in infection experiments proved mostly negative or indecisive. Where they were apparently positive, as with some compounds of the heavy metals, the benefit was ascribable usually to an indirect effect of local tissue reaction or of stimulation of

immunological or other defence mechanisms. The approach of Walbum (1921-9; Walbum and Boas, 1931) mentioned; the use of minute doses of a number of metal certain conditions, especially cadmium and manganese, was to affect the immunological reactions of the body towards infecting tubercle bacilli.

Early Work with Antibiotics

In comparison with the many chemotherapeutic against tuberculosis, using the above-mentioned natural synthetic compounds, reports of results obtained with biotic substances of microbial origin during these 25 years very few; and, reading the literature, one is struck by the of connexion between these two streams of scientific ende-

Rappin (1912), having found that filtered broth cultures of spore-forming bacteria—*B. subtilis*, *B. mesentericus*, and *B. ltherium*—were active *in vitro* against *M. tuberculosis*, in tubercle-infected guinea-pigs with culture filtrates from *B. lthericus*, and reported that the disease was thereby prevented suppressed and that no toxic manifestations followed the injection. About the same time another Frenchman, Vaudremer (191) described a substance obtained from *Aspergillus fumigatus* contact with which tuberculin was inactivated and tubercle lost "their pathogenicity for guinea-pigs and rabbits." Alt Vaudremer apparently made no direct protection experiments infected animals, he reported that clinical trials of his extract in progress in cases of pulmonary tuberculosis in Paris hospital the extract was well tolerated, but preliminary results on patients were inconclusive. These, probably the first chemotherapy experiments with antibiotics in tuberculosis, particularly interesting in the light of present intensive laboratory study of the potentialities, both of the genus *Aspergillus* and the *B. subtilis* group of spore-formers, against this mycobacter. Little further progress seems to have been made as an immediate result of the observations of Rappin and Vaudremer, and in of the publications during the next 25 years on antagonisms against tubercle bacilli the antagonist was in the form of whole culture and not the latter's separated antibiotic products. These results provide evidence of lysis, death, or loss of virulence of tubercle bacilli produced by cultural association with, or by addition the antagonistic micro-organism: the latter included *B. subtilis* (Van Canneyt, 1926; Schiller, 1930); *B. mycoides* (Much Sartorius, 1924; Kimmelsstiel, 1924); "*B. tuberculoiphilus*" (Pum and Favia, 1934); an anaerobic bacillus (Passini, 1926); *Escherichia coli* (Peretz, Newler, and Larionow, 1936); a staphylococcus designated *M. antibioticus* (Dujardin-Beaumetz, 1932, 1934); and yeast (Schiller, 1925, 1927). It may be noted that culture filtrates from Much's cytolytic bacillary strains were active as well as whole cultures, and that a lysate of tubercle bacilli was used in human therapy; while in Schiller's experiments with yeasts and *B. subtilis* the organism to be attacked apparently played a part in "forcing" the antagonism: but neither of these authors produced clear evidence of inhibition of the tuberculous process in the body through antibiotic effect.

While the tremendous amount of information accumulated by all this anti-tuberculosis chemotherapeutic research has been and will be of considerable value, and some of the synthetic and natural substances are being submitted to further study and development, the sum total of short-term practical gain to the clinician must, in retrospect, be regarded as meagre. A number of the drugs investigated in the laboratory found their way into contemporary therapeutics, often without full justification, but their favour was mostly short-lived or local; and the same applies to Vaudremer's antibiotic. The outstanding exception was gold therapy.

The "Gold Decade"

The years 1925-35 might be termed the "sanocrysin" or "gold" decade in tuberculosis treatment. The more recent background to that period was as follows. Koch in 1890 reported that simple gold salts were strongly inhibitory to the growth of tubercle bacilli *in vitro*, but ineffective in experimental tuberculosis in guinea-pigs. Nevertheless, success was claimed with gold salts in phthisis by some clinicians of that time (see above). Spiess and Feldt in Germany during the 1914-18 war recommended a gold-canharidin compound, followed (Feldt, 1917) by an aromatic compound of gold called "krysolgan," which was used principally in German clinics but had lost much of its popularity by the time "sanocrysin" became general. While highly active *in vitro*, this compound's introduction into clinical practice had a rather insecure foundation in animal experiments. Meantime De Witt, in the

U.S.A., investigated various gold compounds in experimental tuberculosis, with negative results, so that gold therapy did not look promising (De Witt *et al.*, 1916, 1918; De Witt, 1918). Then, in 1923, Möllgaard introduced a preparation of sodium aurothiosulphate as "sanocrysin," believing this to be the answer in Ehrlich's sense—i.e., a substance that would reach and attack the bacilli, active *in vitro*, and able to prevent the experimental disease in animals without serious damage to the host's tissues. Rarely, wrote Secher (1927), who first applied the drug clinically, had a therapy been so well based on experimental work. Subsequent events threw doubt on this assertion, for while some eminent workers (e.g., Madsen and Mörch, 1926-7) confirmed and extended Möllgaard's striking claims in experimental tuberculosis, others reported in an opposite sense, and Okell and Parish (1931) concluded that "tuberculosis in guinea-pigs is not influenced by sodium aurothiosulphate." Again, the *in vitro* inhibitory action of sanocrysin was found to be markedly affected by body constituents, etc., and the view gained ground that its action *in vivo* was not directly bactericidal but was indirect, through stimulation of tissue cells, possibly of the reticulo-endothelial system, or through excitation of hyperaemia in the tissues round the tuberculous foci, rather as tuberculin and other salts of gold and various heavy metals were presumed to act (see Cummins, 1930; Wells and Long, 1932).

Sanocrysin was given to the medical world in 1924 as a specific, and most of the profession accepted it, partly perhaps as a welcome change from tuberculin. Möllgaard's preparation was followed by others from various sources, some of which could be given intramuscularly instead of in the vein. A mass of papers was published (those up to 1933 are reviewed by Cummins, 1933). Gold caught the public imagination, as is evidenced by the popularity of the rhymes technical and not so technical that were written around it.

After a period of rather indiscriminate application with high dosage, a more cautious attitude gained ground; and more mature views as to the best indications for gold therapy in pulmonary tuberculosis may be expressed as follows (there being some overlap): (1) in recent "exudative" lesions; (2—perhaps the best indication) to check exacerbation—e.g. in subacute or chronic disease with fresh spread; or in contralateral extension occurring in the course of pneumothorax treatment; (3) to check constitutional disturbance. Gold was, however, persistently used in a variety of cases, in some of which it could, at the best, provide only a placebo.

Although the fatalities of the earlier years were reduced by general acceptance of smaller dosage, objectionable and sometimes dangerous acute or subacute complications were increasingly and persistently reported. The recognition of toxicity, and the inconclusive nature of the benefit conferred, were the main factors in the decline in the use of gold in tuberculosis.

A rough measure of the waxing and waning of interest in this therapy is given in Fig. 1, which shows, from 1925 (when sanocrysin

there is a steady decline up to 1939 and after. It will be seen further that, after a virtual absence during the first six years of papers reporting primarily on toxic effects, their number rises and remains a substantial proportion of the total. The low level of the curve of publications at its end-point is a reflection of the fact that at the present time gold is seldom used for the commoner forms of tuberculosis, except by a few stalwarts: thus, inquiry at three large county tuberculosis institutions in the London area elicited that in 1944 the percentages of patients discharged in whom gold therapy was used were 3.1 (Clare Hall), 0.9 (Harefield), and 0.7 (Colindale), as compared with corresponding percentages in 1938, in the first two hospitals, of 17.8 and 5.7.

This astonishing acceptance of a remedy, and its subsequent rejection without any immediate better substitute, is only equalled by the preceding, but overlapping, dramatic rise and fall of tuberculin therapy. I have considered this phase at some length because the several probable explanations serve also as a lesson for future chemotherapeutic assessments. (1) The laboratory groundwork on the curative effect of sanocrysin was insecure, and the drug was heavily sponsored for general therapeutic use without adequately critical clinical trials. (2) The drug's toxicity relative to presumed effective dose was at first underrated. (3) The clinical benefit was not dramatic or constant enough to dispense with balanced controls, which were in fact rarely used, and where they were (Amberson *et al.*, 1931) the results were discouraging. (4) Investigation was rendered difficult because, as Cummins (1933) points out, pneumothorax treatment (which was extending rapidly contemporaneously) was naturally given preference, with the result that sanocrysin tended to be elbowed out and to be used on the less favourable forms of the disease, in which assessment of effect is equivocal; this is less likely to happen now when the more discriminating use of collapse therapy leaves opportunity for many early cases to be submitted to controlled chemotherapeutic test.

Opinion is still divided on the real value of gold therapy in pulmonary tuberculosis. A few—e.g., Cohen (1943)—hold that, prudently administered on judiciously selected cases, it still has a place; but the undoubted majority consider that, although, like tuberculin, it may produce some advantageous effect in certain types of lesion, the danger makes the risk hardly worth taking.

To bring the use of heavy metals up to date, I should add that (in addition to Walbum's special application) cadmium has been advocated as a less toxic substitute for gold, but without finding much general favour (see Heaf, 1937; Cornwall, 1938; Schedtler and Rodiger, 1941).

The End of the Period

The end of this section of our survey—1935—saw a general and probably healthy reaction among clinicians against drugs in tuberculosis, apart from a few valued symptomatics. The lack of a scientific basis for most of the traditional empirical "specifics" mentioned earlier had won more or less general acceptance among the medical profession, with their consequent virtual disappearance from therapeutics. Two important exceptions were cod-liver oil, still enjoying world-wide repute, and calcium preparations (e.g., calcium gluconate), strongly advocated in some Continental countries. Replacements of the traditional remedies by newer drugs reported on favourably from the laboratory, sometimes on inconclusive evidence, had been limited and temporary. The crest of the wave of interest in gold therapy had been passed. If we add to this negative list the fact that tuberculin as a means of treatment had been generally abandoned except for certain eye, genito-urinary, and other special conditions, a diminution in faith in the specific approach—immunological or chemotherapeutic—to the treatment of tuberculosis is hardly surprising. "No treatment at present can be aimed directly against the causal agent . . ." concludes Browning (1935) in a lecture on chemotherapy; "immunization does not appear to influence the established disease, and the only procedures commonly approved consist in conserving general health, resting affected parts, and removing necrotic tissue"; but he adds that "it is difficult to believe that we must remain bankrupt in methods of directly attacking the tubercle bacillus."

Positive advances in other fields of anti-tuberculosis activity during the preceding 25 years provided compensation for the

FIG. 1.—Graph showing the number of papers on gold treatment in tuberculosis listed in the *Index Medicus* during the years 1925 to 1944.

was first in general use) to 1944, the total annual number of papers referred to in the *Index Medicus* under the heading "Gold Therapy in Tuberculosis," and the number of papers dealing primarily with toxic effects. The graph shows a first wave of publications, then a decline, then a second wave reaching its peak in 1934-5, after which

setback in specific treatment. Sanatoria had expanded in number and developed in scope, both for pulmonary and for non-pulmonary cases. In Britain the National Tuberculosis Scheme, inaugurated in 1912, had proved its worth. Artificial pneumothorax and other forms of collapse therapy had come into their own, particularly from 1920 onwards, when radiographic control became reasonably practicable. Much greater emphasis was being laid upon preventing the disease by reduction of contagion and by insistence on contact examinations. The understanding of the immunology and epidemiology of tuberculous infection had been advanced by the work of Ghon, Opie, Cummins, and many others.

[Part II, with a full list of references, will appear in our next issue.]

WEIL'S DISEASE: A RARE CONDITION?

BY

KENNETH ROBERTSON, M.D., M.R.C.P.

Honorary Physician, Royal Hants County Hospital, Winchester,
and Royal South Hants Hospital, Southampton

An attempt is here made to establish a number of conclusions relating to this disease, which is still generally regarded as of academic interest only. In the first place, we are convinced that the infection is not by any means a rare one, nor is it likely to be encountered only by those whose work brings them into contact with certain industrial groups, such as sewer workers and miners. Secondly, we believe that it is not unreasonable to expect a diagnosis to be made within the first few days of the illness upon clinical methods alone, and that the only requirements are a familiarity with the characteristic picture as seen at this stage of the disease and a knowledge of a number of special points to be looked for and of simple laboratory investigations which must be carried out. Thirdly, as a result of our early recognition of suspected cases we have had the opportunity of watching the effect of specific treatment given at this stage of the infection, and our observations have left a feeling of confidence that this is of real value and may even be life-saving. Finally, as a result of considerable familiarity with the condition, a number of observations have been made which we believe have not been recorded before. We feel that a note on these may be of value.

Frequency of the Disease

In July, 1936, when Weil's disease was to us nothing more than an almost forgotten name, a case came under our care which proved to be a very typical example of this illness. A year later a second case was recognized, and by June, 1938, we had dealt with four such cases. These four cases were of particular local interest, for it appeared that in each case infection had been the result of bathing or working in the same stream (Robertson, 1938). During the next seven years a further 30 cases have been seen—that is to say, we have been encountering the condition four or five times every year.

So far as we have been able to ascertain, the total number of cases recognized during this time in the area in which our work is carried out has certainly not exceeded 40. These rather remarkable figures can surely indicate only two things: the relative frequency of the infection, and the ease with which it has been able to evade recognition.

Recognition

Excellent accounts of the clinical picture are available in textbooks and have been elaborated by numerous workers elsewhere, so that only a brief reference to this is needed here. The infecting organism, *Leptospira icterohaemorrhagiae*, is carried by the rat, and it can be assumed that something like 40% of all rats are infected. The leptospira leaves its host by way of the animal's renal tract. Human infection occurs as the result of contact with water which has been contaminated by rats' urine. Only fresh water can become infective, as quite small amounts of salt render the organism inactive; while direct sunlight has a similar tendency. Stagnant water is more dangerous than that of a freely flowing stream.

Under these conditions the leptospira can probably survive indefinitely. The incubation period appears to be about ten days.

No age is immune, and we have seen the disease at all ages from 5 to 78 years. Characteristically, the onset is abrupt and the victim has been in good health. The symptoms are high fever, often a rigor, severe headache, generalized pains, not infrequently gastro-intestinal symptoms, haemorrhages from some part of the body, and in about half the cases jaundice of varying degree after the fourth or fifth day. In some of the more severe and jaundiced cases serious renal impairment appears, with an increasing retention of nitrogen, sometimes terminating in anuria. It is in this group of cases that fatalities occur.

It must be emphasized that half the cases, whether treated early or not, show no jaundice at any stage of the illness, and among these the incidence of a lymphocytic leptomeningitis is very high. Probably all cases show a peculiar conjunctival suffusion at some time, though this may be transient and may be missed.

Of particular significance are the muscle pains. These are often intense and may persist for several days. The pains are in muscle and are not related to the joints. During this phase pressure over muscle, particularly in the limbs, is often intolerable, and this objective finding almost always persists for several days after the subjective symptoms have subsided.

The headache is severe and by its occipital predilection suggests meningeal involvement; this is often further emphasized by the presence of neck rigidity and a positive Kernig's sign. These findings usually make lumbar puncture inevitable; indeed, several of our cases reached us with the diagnosis of meningitis already made. The cerebrospinal fluid is frequently under pressure and is always water-clear. Pathological examination even in a case with very pronounced meningism may be quite normal when the routine tests are applied; but more often there is slight increase in protein, with a pleocytosis which may reach several hundred cells per cubic millimetre. The sodium chloride level is always normal. If the urea content of the fluid is investigated it is found invariably to be raised above the level which would be regarded as normal for the patient's age. In the laboratory which carries out most of our work the urea content is determined in all lymphocytic fluids which show a normal amount of chloride. This simple arrangement has been of great help in detecting a few early cases.

Haemorrhages are seen at some stage of the illness in most cases, and these may appear early. They may be from the nose, the gums, the gastro-intestinal tract, or into the skin and mucous membranes. When herpes labialis is present it is often haemorrhagic. In some cases a curious mottled appearance of the palate is seen; this was first pointed out to us by Dr. Evan Jones, and has been seen four times. It has not been possible by haematological investigation to determine the cause of this tendency to bleed. Bleeding times, clotting times, and platelet counts have always been normal; the prothrombin level has not been estimated in our cases.

The urine usually shows the presence of albumin, often cylindruria is observed, and not infrequently red cells are present, but a normal urine does not exclude the diagnosis. Often the white cell count is unaltered in the first few days. This statement is the reverse of what has usually been recorded, but time and again we have noted this normality. When jaundice has appeared the rule is a polynuclear leucocytosis, thus helping to differentiate leptospiral jaundice from that due to infective hepatitis. By far the most important single pathological investigation is undoubtedly the determination of the blood urea level. In all our cases this has been raised from the earliest stages, and the level to which this has reached has always provided a useful indication of the severity of the infection.

It should be possible to detect the infecting organism in the blood stream during the first five or six days of the illness, either by direct examination of blood smears with dark-ground illumination methods, or by animal inoculation of the infected blood. We have been successful only once in this, and then by the latter method. It is our view that these diagnostic methods are unnecessary.

Finally, when suspicion has been aroused, a most careful inquiry into the patient's work, home surroundings, and habits with regard to bathing, etc., in fresh water must be made. In nearly all our cases there has been some quite obvious source of possible infection; and in those suspicious cases where no such possibility has been obvious we have almost always failed to prove the diagnosis. We regard this part of the investigation of cases as of the utmost importance.

It is well known that during the septicæmic stage of the illness—that is to say, during the first five or six days—antibodies upon which the diagnostic agglutination reaction depends have not developed in sufficient amount to give a positive finding even at the lowest dilutions. It is therefore useless to expect such a finding until after this stage is over.

At this point I would like to record our deep appreciation of the help we have received from Dr. J. C. Broom and his colleagues of the Wellcome Research Institution, who have carried out all our serum testing for us.

At the appropriate time blood has been sent to Dr. Broom for agglutination testing. Where possible, samples have been forwarded at intervals. This has been done for two reasons. In the first place, a rising titre at which agglutination can be demonstrated is clearly of more diagnostic value than any single test, and, in the second place, we have observed that in the more severe cases the first positive finding has not appeared at the usual time—that is to say, the fifth or sixth day—but has been delayed for several days. In one fatal case the test was negative on the 9th day but positive 1:100 on the 11th, death ensuing on the following day. In another fatal case the test was negative on the day of admission to hospital—the 7th day of illness—positive 1:30 on the 8th day, 1:100 on the 9th, and 1:300 on the 10th, the day of death. In yet another case seen recently the patient's serum showed a mere trace on the 8th day but was positive 1:300 three days later, when heart blood was taken as the patient was actually breathing his last.

We have been quite unsuccessful when attempting to demonstrate the leptospira in patients' urine. It should be possible to do this for varying lengths of time after the first week; but the urine must be freshly passed and neutral in reaction.

Personal Diagnostic Experience

With growing familiarity with the disease an increasing number of cases are diagnosed early. About 70% of our cases were suspected within forty-eight hours of being seen. Some of these cannot qualify as early cases as they did not reach us until late in the illness. Nearly 50% of our cases have been diagnosed within the first four days of the illness and specific treatment started. We believe that this facility in diagnosis is rapidly achieved after quite brief contact with the condition: succeeding house-physicians very rarely failed to detect suspicious cases, and after leaving our district they continued to make the diagnosis with accuracy in other places.

Dr. Broom, in a personal communication, mentions that he has on a number of occasions noticed that positive sera have been received in his laboratories from districts where previously the infection had not been noted, only to find that these sera have been sent to him by doctors who had worked as colleagues with us in this district.

Treatment

Writer after writer has lamented that specific treatment in the early stage of the illness is almost impossible because of diagnostic difficulties. Hutchison, Pippard, Gleeson-White, and Sheehan (1946), record the treatment with penicillin of 6 out of 17 cases appearing in British soldiers in Italy. They state that "unavoidably penicillin could not be started in the pre-icteric stage, but between the 6th and 10th days of the illness." In 1934 Davidson *et al.* wrote: "Hence it appears to us that the clinical diagnosis in the early stage, before jaundice occurs, presents almost insuperable difficulties. Accordingly the full benefit of serum treatment is unlikely to be realized."

Of our cases 12 have been given specific antileptospiral serum during the first four days of the illness, and one other received penicillin within the first two days. In this group there has been no mortality. This compares favourably with the remainder of our cases—about a score—none of which

received treatment until after the fourth day, and among which there were six fatalities—a mortality of 30%.

The story of one very severe case seems to support our impression that serum given early can influence the infection.

In October, 1942, Mrs. F., aged 20, who had had an attack of abortus fever ten months previously, was admitted after three days' high fever. She was very ill, and our investigations seemed to support our suspicion that she was suffering from Weil's disease. Intensive intravenous serum treatment was started at once. She became jaundiced two days later, and finally anuric with a blood urea of 295 mg. per 100 ml. Certain special measures, which will be referred to later, were instituted in an attempt to re-establish renal function. These were successful. She had received 480 ml. of serum, all given intravenously. A week later there was an abrupt rise of temperature with clinical deterioration. The titre of her abortus reaction rose steeply, and it was thought that possibly her old infection had been reactivated. Consequently she was treated with intramuscular "soluspesatine." As this failed to produce the usual rapid reduction of the fever we were driven to the conclusion that her relapse represented the commonly seen secondary rise of Weil's disease. She was desensitized and further intravenous serum given—in all 280 ml. Her fever fell by crisis in twenty-four hours, and she gave no further anxiety.

Penicillin

Alston and Broom (1944) reported that nine strains of *L. icterohaemorrhagiae* and one of *L. canicola* were found to be sensitive to penicillin *in vitro*, and that penicillin exerted a protective action in guinea-pigs infected with leptospira provided treatment was started within twenty-four hours of infection.

Lloyd Hart (1944) reported the rapid disappearance of organisms from a patient's urine after the use of penicillin given late in the illness; and Baldry, in a personal communication, stated that a severe case was treated with penicillin rather late in the illness, apparently with immediate improvement, followed by deterioration when penicillin was withdrawn, and subsequent complete recovery consequent upon the re-establishment of penicillin treatment in larger doses. In the Italian cases already referred to the workers were not impressed by the effect of penicillin given in the icteric stage.

On July 24, 1945, a boy aged 8 years was sent into hospital as a suspected case of Weil's infection by Dr. Loveless, of Stockbridge. He had been ill for forty-eight hours. Our own examination and investigations proved the suspicion to be correct by the finding of a strongly positive agglutination reaction. Penicillin in 20,000-unit doses was given every three hours from July 24 to 28. The boy's temperature, which was 103° F. (39.4° C.) on admission, was normal within twenty-four hours. His blood urea, which had been 65 mg. per 100 ml. on admission, had fallen to 35 mg. by the 29th, and he was discharged from hospital in full health on Aug. 1. No observations of any importance were subsequently made.

Little can be judged from a single case, but it should be noted that the infection appeared to be a severe one, as judged both by the clinical condition and by the blood urea level of 65 mg. per 100 ml. within forty-eight hours of the onset. Furthermore, in spite of this, his fever lasted only three days, as compared with the usual five or six days, and he developed no icterus. One was certainly left with the impression that a severe case had made an unexpectedly rapid recovery. Penicillin was given to two other late cases, when icterus had been established for several days and nitrogen retention had become extreme, with no suggestion of benefit. In one other case, mentioned on page 812, penicillin was given on the sixth day after serum had failed to influence an unusually prolonged febrile stage. The temperature fell by crisis, but there was no clinical improvement, and the boy died the next day, non-icteric.

A farmer of 53, seen in October, 1946, had been treated with 50,000 units of penicillin every four hours from the second day of an acute febrile illness. He became anuric on the seventh day and secreted no urine for 36 hours. Clinical jaundice was not present. When I saw him, on the ninth day, diuresis had set in and his temperature had subsided. A petechial rash, haemorrhagic herpes, and slight conjunctival icterus suggested that he was suffering from Weil's disease. His blood urea on that day was 250 mg. per 100 ml. and he had an icteric index of 11 units. His blood agglutinated leptospira up to a dilution of 1:1,000. There was no further rise in his icteric index, and he has made a good recovery.

The importance of this case appears to be the suggestion that the penicillin had protected his liver while failing to prevent

the renal complications. We have never seen blood urea figures approaching 250 mg. in any case which was not frankly jaundiced, except for the fatal case reported in this paper.

These observations, taken with the experimental evidence reported by Alston and Broom, strengthen our belief that, provided it can be used during the early septicæmic stage and that it is used freely, we have in penicillin a specific of probably greater usefulness than serum. It may well be that the best results will be obtained by a combination of both agents.

Other Points about Treatment

In addition to the questions relating to specific treatment, a number of observations have been possible with regard to the more general aspects of treatment. Immediately a diagnosis has been made—indeed, when it remains only a suspicion—the patient should be put on a low-protein diet. Fluids should be pressed and glucose used freely. The urine should be rendered alkaline by the use of potassium citrate, and a very careful intake and output record should be kept for each twelve hours. At the first sign of a falling output more drastic measures to overcome this should immediately be started. We have found valuable the free use of 50% glucose intravenously, and it is our habit to give 50 ml. every eight hours. We have not hesitated to employ continuous intravenous drip methods, using saline, glucose-saline, plain glucose, and sodium sulphate, great care being taken to maintain a proper salt balance in order to avoid pulmonary complications. This last is of particular importance, as the bad cases have frequently shown pulmonary congestion, and even consolidation, quite apart from intravenous therapy. We have used heat and even short-wave diathermy to the renal areas, and have brought heat to the kidneys from in front by means of hot colonic irrigation as suggested by Hamilton Fairley.

Finally, we have in three desperate cases attempted by the use of high spinal analgesia to re-establish renal function by invoking sympathetic release. In each of these three cases the anuric state gave place to secretion following the spinal analgesic. In one—Mrs. F., already referred to—this went on to full renal function and complete recovery; but in the other two, both of whom showed blood urea figures of over 500 mg. per 100 ml., in spite of restarting secretion recovery did not follow. One of these men excreted 30 oz. (0.85 l.) of urine on the day before death, and his blood urea had fallen.

The value of high spinal analgesia in certain cases of anuria was well shown in the case of a 5-year-old girl who had sustained an extensive third-degree burn of the thigh. Five days after her accident she was found to be completely anuric and her blood urea had reached 520 mg. per 100 ml. Three days later, after complete failure of all other methods of treatment, high spinal analgesia was induced, with subsequent re-establishment of renal function and ultimate total recovery. In using this drastic method of treatment anxiety is bound to be experienced, as these cases invariably have a very low systolic pressure. Figures as low as 70 mm. Hg systolic have been seen. We have used injections of ephedrine before and during the treatment. In future we propose to use this method earlier in the threatening cases rather than leave it as a last almost hopeless attempt to save life.

It seems clear that the anuric state seen in the more severe cases will have to be regarded as an example of what Maegraith and others (1945) have called the "renal anoxia syndrome"; the appearance, naked-eye and microscopical, of the kidneys in fatal cases being to all intents and purposes identical with that seen in conditions such as crush syndrome, blackwater fever, incompatible blood transfusion, and so-called traumatic uræmia.

The part, if any, played by spinal analgesia or splanchnic block in the therapy of this condition is not as yet clear, but it should be recalled that in discussing this syndrome following trauma Trueta suggests the possibility that vascular spasm is in part responsible. Our results with spinal analgesia would seem to support this suggestion.

Serum Diagnosis

The final diagnosis in our cases has always rested upon the demonstration of agglutinins, if possible in rising titre, in the patient's blood. It has been suggested from time to time that where specific serum has been given this may influence such

investigations, possibly falsifying diagnosis. This possibility is freely admitted, though in 1934 Schüffner, speaking of individuals incorrectly treated with serum and later proved not to be suffering from leptospiral infection, stated that in these people the agglutination reaction remained negative.

Alston (1940) carried out an experiment with rabbits in an attempt to determine the fate of specific antileptospiral serum. In four animals used, a positive agglutination reaction was obtained immediately after a test dose of serum. The titre of this reaction subsequently fell rapidly, and at the end of 12 hours antibodies could no longer be detected. In an attempt to repeat this experiment in the human subject 100 ml. of antileptospiral serum was injected intravenously into a patient suffering from influenza. Blood was tested for the presence of agglutinins at intervals of five minutes, one hour, twelve hours and twenty-four hours after the serum injection. Though they were present in considerable concentration at five minutes and one hour, there was a steep reduction at twelve hours, and at twenty-four hours they had almost disappeared from the blood. In our case a dose equivalent to about three times the dose used by Alston, and considerably in excess of the usual therapeutic dose, was given, while the fall in titre seems to have been even more rapid than in the animal experiment. If more than one test is carried out, and a rising titre is obtained, we feel that this possibly disturbing factor in diagnosis can be safely discounted.

It must be remembered that a previous infection may be responsible for a positive agglutination reaction. Our first two cases had positive agglutination three and four years respectively after their illness, though not in high dilution. In such a case a rising titre would be required to establish the diagnosis, though, so far as we know, no case of second attack has ever been recorded.

Schüffner's often-quoted dictum, that where there is a icterus there is no mortality in this illness, is almost invariably correct. Indeed, we can find no reference to any fatal non-icteric case from the British Isles. This makes the following story seem worthy of mention:

In November, 1944, a boy of 15 was admitted to hospital on the surgical side with a tentative diagnosis of acute appendicitis. He had then been ill for three days and his temperature was 103° F. (39.4° C.). His white cell count showed 4,700 leucocytes with a normal differential count. His temperature was maintained and three days later we were asked to see him as he had developed a generalized rash, and the question of measles had been raised.

Upon examination he was clearly very ill. The rash was morbilliform and generalized, but the buccal mucosa showed no change. Furthermore, he had had measles three years before. His white cell count had risen to 12,700, with 95% of polynuclears. His blood urea was 73 mg. per 100 ml., and the icteric index 4 units; the urine showed a cloud of albumin only.

This was now the sixth day of his illness and blood was sent Dr. Broom for testing. This first sample gave a very weak positive reaction at 1:10. Serum treatment had been started at once, but the boy's condition had deteriorated by the next day and his blood urea had reached 146 mg. per 100 ml. His temperature showed a sign of falling. Penicillin was substituted for serum, and though his temperature became normal in about 12 hours he continued to go downhill, and died on the eighth day of illness.

Two subsequent agglutination tests were both positive at 1: and 1:30 respectively. At no time was any suggestion of jaundice noticed, and his icteric index remained within normal limits.

Dr. Broom, in a personal communication, says that he has sometimes seen guinea-pigs infected with leptospira die very quickly and without the development of either jaundice or haemorrhages, as if they had been overwhelmed by the toxæmia before there had been time to develop the usual signs. Such, we feel, must have been the experience of this boy. Unfortunately it was not possible to carry out a necropsy in his case.

Weil's disease is not included in the schedule of diseases which call for notification under the Industrial Diseases Act in England, but in cases where it is possible to establish that the victim contracted his infection while at work the employer's liability under the Workmen's Compensation Act is obvious. In one of our fatal cases, that of a farm labourer who had been employed in thatching ricks about the time when he probably became infected, the judge in the Winchester County Court supported the claims of the appellants, and the man's widow

was granted a considerable sum in compensation for the loss of her husband. In two subsequent fatal cases, and under almost identical circumstances, it appears that the insurance companies concerned do not propose to question their liability, though a careful scrutiny of the cases has been made from the diagnostic aspect. Thus the need for solid and unquestionable diagnosis in these cases becomes of more than purely medical and scientific interest.

Since the writing of this paper Williams has treated a severe case of Weil's disease in a man of 53, deeply jaundiced, oliguric, and with a blood urea of over 300 mg. per 100 ml., by methods devised to raise the blood pressure—intravenous plasma and injections of ephedrine, combined with high spinal analgesia. The result was dramatic. There was no further increase in blood urea, and within twelve hours a considerable diuresis had been established which went on to a veritable deluge, with rapidly falling blood urea and uninterrupted recovery. This case, as judged by all the standards which our experience in the past had led us to accept as of importance prognostically—age, depth of jaundice, degree of nitrogen retention, and absence of early specific treatment—caused us to predict a fatal outcome. This prognostication was triumphantly disproved by the course of the illness.

No case has come under our care since the publication of Zondek's (1946) stimulating paper on extrarenal azotaemia and extrarenal uraemia, so that we have had no opportunity of investigating his suggestions with regard to Weil's disease, though we have fully confirmed his findings in severe gastrointestinal bleeding and relapsed pernicious anaemia, in which the normal relationship between the urea and chloride excretion has been grossly disturbed in the direction of relatively reduced chloride excretion. Nevertheless, we feel confident that his findings would almost certainly be available in these cases, as the urea content in the urine of oliguric patients has always been above 2%.

Our observations in this disease lead us to believe that the mechanism of cortical renal ischaemia, as described by Trueta and others (1946), is of great importance in the aetiology of the syndrome of water and nitrogen retention seen in the more severe cases of this infection, and the explanation of the apparent success of spinal analgesia in these cases becomes more easily understandable. This work appears to emphasize the need for earlier use of this method of treatment in oliguric cases.

I would like to record again my sense of indebtedness to Dr. J. C. Broom for all his help and encouragement in this work. Dr. Wrigley, Honorary Pathologist, Royal Hampshire County Hospital, has been responsible for all the other pathological work done in our cases, and my sincere thanks are due to him. I am most grateful to numerous house-physicians for their help, and to the local practitioners who have been responsible for referring cases to me.

In pursuance of the statutory procedure under the Factories Act, 1937, the Minister of Labour and National Service proposes to make, under Section 65, regulations entitled the Dangerous Occurrence (Notification) Regulations, 1946. The Dangerous Occurrences (Notification) Order, 1935, which would be revoked, extended the provisions with regard to notice of accident to the same classes of occurrences as are specified in the Schedule to these Regulations. The Order was, however, limited to factories or workshops within the meaning of the Factory and Workshop Act, 1901, and places which, for the purpose of the provisions of that Act with respect to accidents, were a factory, or workshop or were part of the factory or workshop. The proposed Regulations require notification of the same classes of occurrences happening in factories as defined in the Factories Act, 1937, or in premises or places, or in the carrying on of processes or operations or work, to which Part V of that Act (which relates to the notification and investigation of accidents and industrial diseases) is applied by Sections 103 to 108. Copies of the Regulations may be had from H.M. Stationery Office or through any bookseller, price 1d.

AN UNUSUAL CASE OF WEIL'S DISEASE

BY

HAROLD JACKSON, M.B., Ch.B., M.Sc., Ph.D.

Late House-Physician, Manchester Royal Infirmary

AND

SAMUEL OLEESKY, M.B., Ch.B., B.Sc., M.R.C.P.

Late Resident Clinical Pathologist, Manchester Royal Infirmary

Evidence is accumulating which indicates that Weil's disease is not rare in this country. Gardner and Wylie (1946) report that over the past six years they have examined 182 sera which gave positive serological evidence of Weil's disease, and also that in various laboratories throughout Great Britain and Northern Ireland 488 cases have been serologically diagnosed during this period. It is probable that many mild and anicteric cases have escaped diagnosis. The present case is being recorded in order to stress the need to consider Weil's disease in the differential diagnosis of any case of jaundice or nephritis, and to report the occurrence of the clinical syndrome of bilateral adrenal haemorrhages in Weil's disease.

Case History

The patient, a heavily built man aged 56, was a butcher living in a village twenty miles from Manchester. For some days before the onset of his illness he had felt unusually tired, but continued normally with his work. On Oct. 25, 1945, he had a severe frontal headache, and the next day, having developed a high fever, he sought medical advice. On Oct. 29, the fever having persisted, a course of sulphapyridine was started, a total of 16 g. being given in four-hourly doses. On this day he began to vomit frequently, and, in his own words, "it has been a case of drink and vomit since." The vomitus became greenish black with a foul smell, and was described by a visiting relative "as if his motions were coming up the wrong way." In view of the vomiting it is difficult to say how much of the sulphapyridine was retained. On Oct. 30 jaundice started, and the patient was troubled by a persistent hiccup. No urine had been passed since Oct. 28, apart from a few drops of blood-stained fluid, and he had been constipated throughout the illness except for a small dark stool on Oct. 30.

The patient was admitted to the Manchester Royal Infirmary on the evening of the 31st, and died twenty hours later. On admission he was mentally clear but extremely anxious; retching and hiccup were frequent, and he complained of an intense thirst. The temperature was 96° F. (35.6° C.), pulse 130, and respirations shallow at 30 to the minute. On examination the most striking feature was jaundice. There was severe circulatory collapse, the pulse was thready, the extremities were very cold, and the systolic blood pressure was only 80 mm. Sweating was profuse yet dehydration was severe. The tongue was dry but clean, and the conjunctivae were congested. The pupils were constricted, probably as a result of morphine given before the journey to hospital.

Examination of the abdomen revealed numerous small purple petechiae on both flanks. No marked distension or rigidity was observed, but there was great tenderness. The liver was not felt—in fact, it seemed as if the area of liver dullness was diminished. No significant physical signs were found in the chest or central nervous system. A provisional diagnosis of acute hepatic necrosis or hepato-renal syndrome was made. Soon after admission it was pointed out that, apart from the jaundice, the general picture suggested acute adrenal insufficiency as in the Waterhouse-Friederichsen syndrome. There was also the possibility that the sulphapyridine administered might be implicated to some degree. Intravenous glucose-saline was given; unfortunately cortin was not available. The white cells numbered 14,200 and the haemoglobin was 13.5 g.%. The next morning he passed half an ounce (14 ml.) of urine, but the state of circulatory collapse continued.

The possibility of leptospiral infection was meantime considered and blood was taken for serological and biochemical investigation. The patient now lapsed into a state of muttering delirium, the pulse weakened and became imperceptible, the temperature rose to 100° F. (37.8° C.), and he died twenty hours after admission.

Laboratory investigations on Nov. 1 showed: W.B.C., 10,600 per c.mm. (polymorphs 76.5%, lymphocytes 10%, monocytes 3.5%, eosinophils 0.5%, myelocytes 6%, metamyelocytes 3%, Türk cells 0.5%, plasma cells 1%, nucleated R.B.C. 5/100 W.B.C.). Haemoglobin, 12.1 g.%. Blood urea, 270 mg. per 100 ml. Whole blood chlorides, 316 mg. per 100 ml. (as NaCl). Serum colloidal gold reaction: 2332110000. Van den Bergh test: immediate direct reaction with maximum colour in two minutes (bilirubin 32 mg. per 100 ml.). Serum proteins: albumin, 3.2 g.%, globulin, 3 g.%. Urine: centrifuged deposit showed numerous red cells and pus

cells, renal epithelial cells, but no casts. No leptospirae could be found on dark-ground examination, but the urine was examined after some delay.

Serum for agglutination against *Leptospira icterohaemorrhagiae* was sent to the Reference Laboratory at Oxford. The result showed a positive agglutination in a dilution of 1/400; the reaction was a partial agglutination, atypical microscopically.

The necropsy was performed twenty-two hours after death; the report was as follows (Dr. Susman):

Lungs: scattered haemorrhages in both pleurae; both lungs distended with fluid; many haemorrhages throughout. **Stomach:** scattered haemorrhages over the mucosa; massive haemorrhage involving five to six feet (1.5-1.8 metres) of the terminal ileum. **Liver:** enlarged; yellow colour throughout; no macroscopic necrosis; biliary pathway normal. **Spleen:** enlarged; brick-red colour. **Adrenals:** bilateral enlargement; complete disorganization by extensive haemorrhages. **Kidney:** abundant pelvic haemorrhages; fresh fatty degeneration.

Histological Findings.—Liver:—There were dissociation and loosening of the hepatic cells, scattered areas of fatty degeneration, and areas of hepatic regeneration with enlarged and binucleated liver cells. No leptospirae could be found on sections stained by the Levaditi technique. **Kidney:**—There were a few hyalinized glomeruli, some tubular necrosis, scattered foci of polymorph and lymphocytic infiltration, and many dilated blood vessels. Sudan IV section failed to reveal fatty degeneration, but sections stained by the Levaditi technique showed many leptospirae, particularly around the tubules.

The finding of spirochaetes in the kidney but not in the liver, and the rarity of the organisms in the liver, were commented upon by Ashe *et al.* (1941).

Discussion

The clinical history of a febrile disturbance followed by severe renal and hepatic failure accompanied by a haemorrhagic rash, associated with the laboratory and necropsy findings, proves the diagnosis of Weil's disease. The hepatic and renal failure noted in this case has been the subject of previous comment. Ashe *et al.* (1941) speak of a hepato-renal syndrome in the disease; Walch-Sorgdrager (1939) refers to the frequent misdiagnosis of acute yellow atrophy; and Davidson *et al.* (1934) consider the association of jaundice and nephritis of great diagnostic value. The presence of an atypical agglutination of 1/400 against leptospirae is probably explained by the fact that the reaction was performed early in the disease, and in those cases terminating fatally the development of antibodies may be delayed.

This case, with severe peripheral collapse, cold extremities, a low blood pressure, and profuse sweating, resembled clinically the acute adrenal apoplexy of the Waterhouse-Friederichsen syndrome. That syndrome occurs classically in meningococcal meningitis or meningococcal septicaemia, and, so far as we know, this clinical picture has not been reported in Weil's disease, though bilateral adrenal haemorrhages are a common necropsy finding (Ashe *et al.*, 1941).

Gardner and Wylie (1946) found that 3.3% of their 182 cases were in butchers, but did not specify the actual work done by these men. Our case is interesting in that it occurred sporadically in a butcher who did not frequent slaughterhouses or kill his own cattle. A case has been reported in which the infection was derived from meat that had been contaminated by rat urine, and the disease is a known hazard of slaughtermen (Walch-Sorgdrager, 1939).

In order to pursue the epidemiological aspects further, two rats were obtained from behind the patient's home and close to a small stream. On post-mortem examination they were normal, but leptospirae were seen in the kidney on sectioning and staining by the Levaditi technique. The kidneys of the rats were ground up and injected into guinea-pigs, and the latter died on the ninth and tenth days, presenting at necropsy the typical appearances of Weil's disease. They showed jaundice, haemorrhages into the lungs (butterfly appearance), kidneys, and adrenals, and on section the kidneys, liver, spleen, adrenals, and lungs contained numerous spirochaetes. Weil's disease, which is mild and asymptomatic in rats, has an incidence of between 10 and 30% in wild rats in this country, and it is highly probable that infection in the present case was derived from the local rat population.

The death rate in Weil's disease has been variously put between 4 and 48% (Walch-Sorgdrager, 1939; Wood, 1943),

but as more of the milder cases come to be diagnosed it is probable the death rate will fall. It is interesting that most of those who die from the disease have severe renal failure, with associated uraemia and oliguria (Wood, 1943; Hutchison *et al.*, 1946), and the case presented here was no exception to this rule.

Summary

A case of Weil's disease occurring sporadically in a butcher and presenting the clinical signs of acute adrenal insufficiency is described. The importance of considering Weil's disease in the differential diagnosis of jaundice and nephritis is stressed.

We acknowledge our gratitude to Dr. W. Brockbank for permission to publish a report of this case.

GRAVITY DRAINAGE IN THE PRONE POSITION IN TREATMENT OF DIGESTIVE FISTULAE OF THE ABDOMINAL WALL

BY

DAVID H. PATEY, M.S., F.R.C.S.

J. H. L. FERGUSON, M.B.E., M.B., B.Ch.

AND

M. D. EXLEY, S.R.N.

(From the Wards of the Middlesex Hospital)

A fistula of the abdominal wall which communicates internally with a segment of the alimentary canal rich in digestive juices (e.g., duodenum, jejunum, ileum, and to a lesser extent caecum or with a digestive gland (e.g., pancreas), may constitute a serious trial to the patient and a test to medical and nursing attendants. The special feature of these cases is the digestion of the skin which occurs around the fistula, often to a considerable distance. When the discharge is abundant it may flow round the back and down to the groin and crutch, so that areas of skin outside the abdominal wall may also be digested. The raw digested skin is extremely painful and sensitive, and a patient with an extensive digestive fistula is usually miserable and his appetite and sleep are upset. From these causes alone quite apart from any nutritional loss from the fistula, his general condition may progressively deteriorate, and a vicious circle be set up that may preclude the direct surgical attack which alone can cure the fistula. Minor digestive fistulae may lend themselves to treatment by the application of protective or neutralizing pastes and ointments to the abdominal wall; a rather more severe fistula may be successfully treated by some suction method of removing the digestive juices as they exude; but for a real pouring digestive fistula all these methods usually fail.

We have successfully treated a number of cases of this type during the past few years by gravity drainage in the prone position. As this method of treatment of digestive fistulae does not seem to be widely known, we have thought it worth while to record the method, together with some practical points of importance and a review of four cases.

Case I

The first case was the most dramatic, and it was in this one that the method was worked out. It was that of a schoolboy, aged 15, who was admitted on March 7, 1943, from another hospital to the care of Surg. Rear-Admiral Sir Gordon Gordon-Taylor. Three months previously his gangrenous appendix had been removed. Small-gut obstruction and pelvic abscess formation had followed, for which ileostomy was performed. Subsequent attempted closure failed, and a further laparotomy revealed sloughing of coils of small gut which later formed three other spontaneous jejunal fistulae. His condition when first seen was extremely bad. He was distressingly emaciated (weight, 5 st. 3 lb.=33.1 kg.), while, on to his abdominal wall, raw and semi-digested from costal margin to pubis,

quantities of fluid and semi-solid intestinal contents discharged, and the mere approach of a medical attendant caused screams of apprehension. At the same time the boy was ravenously hungry; meals were crupted together with succus entericus on to his abdomen within half an hour of ingestion. During the two days following admission a variety of nursing methods applicable to intestinal fistulae were unsuccessfully adopted. Protective pastes could not adhere to the abdominal wall, oiled-silk sheeting failed to maintain watertight connexion with the indrawn mouths of the stulae, while mechanical suction was subject to obstruction from semi-solid matter and prolapsed intestine and was unable to cope with sudden peristaltic rushes. Local percaïne application did, however, alleviate his pain. Meanwhile a large sacral sore was also causing much distress, and the decision was taken to nurse the patient in the prone position on slings in the hope that the sore could be given an opportunity to heal, and that simultaneously the intestinal contents would discharge downwards from the stomata without further irritation and digestion of the parietes.

Although the success of this measure was immediately evident, the uneven weight distribution with the slings proved uncomfortable to the patient's back. The carpenter then made a special wooden frame. But finally the method described and illustrated was evolved and the boy lay in the prone position day and night almost without interruption for nearly three months.

The improvement of his condition was striking. Six pounds (2.7 kg.) in weight was gained in six days. The abdominal wall began to heal, and it was interesting to note that the intestine prolapsing through hitherto recessed openings formed valves which assisted in slowing the intestinal emptying time, thus aiding nutrition, and occasional rectal motions were achieved. By June 3 his weight was 6 st. 7 lb. (41.28 kg.). Operation, consisting of multiple resection and anastomosis, was possible, and with saline, glucose, plasma, blood, and sulphamezathine preparation this was successfully performed by Sir Gordon Gordon-Taylor. When last seen in February, 1944, the boy was in excellent health and spirits.

Case II

This patient was a man aged 49 on whom laparotomy had been performed with a view to resection of a gastric ulcer. Owing to the size, difficult access, and adhesions it was decided to do a jejunostomy instead, by cutting across the jejunum and making an anastomosis in Y, bringing the cut distal end out through the abdominal wall. Owing to the extreme regurgitation of digestive juices the jejunostomy was not a technical success. The abdominal wall, groins, and back became very raw. The patient was nursed in the prone position, when the condition of the abdominal wall at once improved and it was found possible to maintain the jejunostomy feeding for nearly five months. It was then operated on uneventfully and closed.

Case III

This man, aged 25, had a terminal ileostomy performed in May, 1943, for acute ulcerative colitis with haemorrhage which had failed to respond to medical treatment. The abdominal wall became badly digested from the discharges from the ileostomy. Treatment in the prone position rapidly cleared up the condition of the abdominal wall. The patient died in November, 1943, after operation for intestinal obstruction, but the condition of the abdominal wall had in the meantime been satisfactorily controlled by nursing in the prone position.

Case IV

This patient, a man aged 34, also suffered from ulcerative colitis which had failed to respond to medical treatment. Terminal ileostomy was performed in June, 1945, and again there was much digestion of the abdominal wall by the small-intestine discharges. Treatment in the prone position was successfully adopted, and was carried out with intervals over several months. At the end of this time the ileostomy discharge was semi-solid and much less irritating. Subsequently total colectomy was successfully performed. In this case the prone position did lead to a moderate prolapse of the ileostomy, up to about 6 in. (15 cm.) protruding, but this went back when he was able to resume the supine position.

Some Practical Points

The accompanying illustration shows the arrangement of the bed and mattresses that was found to be the simplest and most efficient. The mattress at the head of the bed is the top third of a divided mattress, and that at the bottom an ordinary mattress folded as illustrated so that the dorsa of the feet are comfortably supported. A flat tray can thus be introduced between the two mattresses to catch the discharges. In addition pillows may be arranged round the division in the mattresses to suit the comfort of the patient. He may lie in this position continuously day and night as the first case did, or may be turned back for intervals of rest. The worse the state of the

abdominal wall the less he feels the inconvenience of the abnormal position in the relief it affords. In a total intestinal fistula the bowels present no problem. In a partial intestinal fistula the patient is turned when he wishes to open his bowels. The prone position with divided mattress lends itself without difficulty to the passage of urine in the male (it so happened

Diagram showing arrangement of bed and mattresses.

that all our patients have been males), and it should not be difficult to make suitable nursing arrangements in the female. Meals can readily be taken prone if the food is first cut up and the pillows are adjusted, the patient supporting himself on one arm and using a spoon with the other hand. Reading can be managed with a book-rest. It is best to turn the head end of the bed to the centre of the ward so that the patient sees the activities of the ward and not merely the wall.

A CASE OF CEREBRAL MALARIA IN GREAT BRITAIN

BY

J. B. RYDER, M.R.C.P.I.

AND

R. T. TOWSON, M.D.

Assistant Medical Officers, South Shields General Hospital

Cerebral malaria as a cause of coma is rare in Great Britain. A search of the literature has revealed only two cases in recent years (Minett and Bernfield, 1937; Sneddon, 1943), in spite of the fact that one would have expected to encounter further cases in Service personnel returning from malarious areas, especially in those repatriated by air. The following case is reported in order to emphasize two important aspects of the condition: first, that it may have to be considered as a cause of coma in this country, and, secondly, because early treatment is so essential.

Case Report

A steward in the Merchant Navy aged 26 was admitted in coma to the South Shields General Hospital at 1.30 p.m. on Sept. 8, 1946. The history, elicited from his wife, was as follows: Four days previously he had arrived in port from West Africa, having been ten days at sea. On reaching home the same day he had complained of headache and of feeling hot and shivery. He had a frequent unproductive cough and vomited after food. During the three succeeding days he had several brief severe shivering attacks and the vomiting persisted. His doctor at first treated him for influenza, but when he suddenly became unconscious, at noon on the fourth day, straightaway sent him into hospital with a provisional diagnosis of malaria. A previous history of an attack of malaria three years before, with no subsequent relapses, was also obtained from his wife, and later confirmed by the patient himself.

On examination he was seen to be a man of average physique. He was in a restless, lightly comatose state, but responded to simple shouted orders and reacted to painful stimuli. He was unable to speak and was incontinent of urine. The temperature was 101.2° F. (38.4° C.), pulse 100, and respirations 28. His skin was dry and hot; no abnormality was found in the cardiovascular system and lungs. The abdomen exhibited moderate muscular resistance in the left hypochondrium, but neither liver nor spleen was palpable. Examination of the C.N.S. showed regular and equal pupils with a sluggish reaction to light; no abnormality in the fundi; normal muscle tone, no paralysis; general absence of tendon reflexes, with

a bilateral extensor plantar response; no evidence of meningeal irritation. Urine, N.A.D.

In view of the fact that he had recently been in an endemic centre of malignant tertian malaria the diagnosis of cerebral malaria was entertained. Blood films were examined and revealed a heavy infection with *Plasmodium falciparum*, numerous ring-stage parasites being present. This finding was later confirmed by Dr. Houston of the Pathology Department, Sunderland Royal Infirmary.

Treatment.—Quinine sulphate 10 gr. (0.65 g.) was given orally at 2 p.m., and the patient was able to take sips of water by mouth. Acid quinine hydrochloride 10 gr. in 10 ml. of sterile distilled water was administered half an hour later by slow intravenous injection. Rectal glucose-salines were ordered four-hourly. At 11.30 p.m. the coma was somewhat deeper and the patient was still restless and incontinent of urine. Temperature 99.8° F. (37.7° C.), pulse 108, respirations 24. He was now unable to take anything by mouth. The intravenous quinine was repeated. On the morning of Sept. 9 his condition was unchanged: Temperature 99.8° F., pulse 104, respirations 24. Neck rigidity had now appeared. Lumbar puncture was performed under local analgesia and 10 ml. of clear fluid under slightly increased pressure withdrawn. As the patient was not now retaining fluids per rectum a glucose-saline intravenous drip was started. He was still incontinent and could take no fluids by mouth. On the morning of the 10th his condition was greatly improved; he was conscious and rational, and taking copious fluids by mouth. Temperature 101.4° F. (38.55° C.), pulse 92, respirations 28. His further convalescence was uneventful, and a standard quinine-mepacrine course was instituted. On the 12th a blood film revealed no parasites; his temperature was 97.4° F. (36.3° C.), pulse 72, and respirations 20, and he was discharged home.

Discussion

In arriving at a diagnosis in this case the following points were of importance: (a) A recent visit to a malarious area; (b) history of headache, vomiting, and rigors; (c) sudden descent into coma. The suspicion of cerebral malaria thus aroused, coupled with absence of the clinical picture of any of the more common causes of coma in this country, led to the examination of blood films with resulting confirmation of the diagnosis.

As the clear-cut history in this instance may not be paralleled in other cases of cerebral malaria occurring in Britain, several other conditions must be considered in the differential diagnosis. The most important of these are:

1. *Meningitis* (in particular the hyperacute and fulminating forms).—The frequent occurrence of signs of meningeal irritation in cerebral malaria may confuse the diagnosis, and a lumbar puncture may be essential to differentiate.

2. *Alcoholic Coma*.—It is stated that cerebral malaria often closely simulates alcoholism. This has resulted in fatalities from misdiagnosis, and emphasizes the importance of examining blood films in doubtful cases of coma.

3. *Cerebral Vascular Accident*.—(a) Subarachnoid haemorrhage: In this condition severe headache followed by rapid onset of stupor or coma is characteristic, and meningeal irritation is usually well marked. Lumbar puncture, however, readily establishes the diagnosis. (b) Cerebral haemorrhage, thrombosis, or embolism: The production of embolism by malaria parasites may lead to various cerebral manifestations, among which hemiplegia, monoplegia, and aphasia have been described.

4. *Uræmia*.—The most likely causes of this condition in young adults are malignant hypertension and the alkali treatment of peptic ulcer associated with renal insufficiency. The onset of coma may be rapid, and prodromata equivocal. Examination of the urine, blood urea, and alkali reserve will differentiate the condition from cerebral malaria.

The present case occurred in a man who returned from an endemic area within the accepted incubation period of the disease, and illustrates the importance of considering a diagnosis of cerebral malaria in cases of coma of uncertain origin, particularly in Service personnel returning from overseas. This is especially important, as early diagnosis and adequate treatment are so essential in a disease which carries a 40% mortality in treated cases (Sanford, Crawford, and Warr, 1940). Endemic cases are unlikely to occur, as tropical strains of the malignant tertian parasite fail to survive in the mosquito at temperatures below 75° F. (24° C.) (Shute, 1945).

The dosage of quinine used in this case was somewhat higher than that advocated by Manson-Bahr (1942)—i.e., 5 to 7 gr. (0.32 to 0.45 g.)—but no untoward reactions were encountered. Intramuscular mepacrine is now being used in preference to intravenous quinine in these cases, as the likelihood of toxic

reactions is even less with the former drug, but it was immediately available for use in this instance.

Summary

A case of cerebral malaria, with recovery, occurring in Great Britain is described.

The differential diagnosis is discussed.

The importance of early diagnosis and prompt adequate treatment is emphasized.

Our thanks are due to Dr. W. Campbell Lyons, M.O.H., St. Shields, for permission to publish this case; to Dr. Houston of the Pathology Department, Sunderland Royal Infirmary, for his report on the blood films; to Dr. N. Strang, deputy medical superintendent who allowed us to treat the case in his ward; and to Dr. Downing, South Shields, who referred the case to us.

KALA-AZAR WITH ONSET OF SYMPTOMS IN GREAT BRITAIN.

BY

A. FELDMAN, M.B., B.S.

Senior Assistant, Rush Green Hospital, Romford, Essex

In view of the return to Britain of many of our soldiers from the shores of the Mediterranean, where kala-azar is endemic, the following case may be of interest. It serves to illustrate the fact that symptoms of kala-azar may not appear for the first time until the patient reaches this country, when the disease may simulate a primary attack of malaria.

Case History

The patient, a man aged 29, served as a soldier in North Africa and Italy for 3½ years. During that time he had no symptoms of illness. He returned to England and was apparently well for four months. On April 18, 1946, he noticed small lumps in both groins, and the next day an attack of shivering and sweating began. He continued having one of these attacks each day, but in spite of them felt quite well. Apart from slight initial nausea his appetite remained good and there were no other symptoms. On April 27 he was sent into hospital as a case of primary malaria.

On admission his general condition was fair. He had a sallow complexion (this became dusky later in the disease), and his tongue was brown and furred. A soft swelling was palpable in the left hypochondrium, extending for three or four fingerbreadths below the costal margin. It was of an indefinite outline, and was first noted as " ? kidney; ? spleen." The liver edge was not palpable at this stage. The inguinal glands were felt to be slightly enlarged. The heart, lungs, and C.N.S. were normal clinically. Temperature, 101.2° F. (38.4° C.); pulse, 104; respirations, 22. During the first week after admission to hospital the patient had an intermittent high pyrexia reaching 102°–103.8° F. (38.9°–39.9° C.), with daily rigors and sweating. Occasionally there were two spikes of temperature during the 24 hours. He continued to "feel fine." By April 30 the mass in the left hypochondrium had increased in size and was obviously the spleen. The liver edge was also palpable for two fingerbreadths below the right costal margin. Skiagrams of the chest showed some congestion at the right costo-phrenic angle (presumably due to the enlargement of the liver); otherwise the chest was clear. A blood count showed: white cells, 2,140 per c.mm. (polymorphs 68%, lymphocytes 29%, monocytes 2.5%, eosinophils 0.5%); red cells 3,650,000 per c.mm.; Hb, 70%; C.I., 0.95. Repeated blood smears were negative for the malaria parasite. The urine showed no abnormality and the diazo reaction was negative.

As a diagnostic measure, starting on May 1, a course of two days' quinine 10 gr. (0.65 g.) t.d.s., followed by three days' mepacrine 0.1 g. t.d.s., was given, with no effect on the temperature. This was followed by penicillin injections (15,000 units three-hourly for 8 days), which proved equally ineffective. On May 2 agglutination tests on the serum were negative for typhoid, paratyphoid, dysentery, and *Brucella abortus* and *melitensis* organisms. Many dilutions were used with the *Br. abortus* to exclude the possibility of a zone reaction. A blood Wassermann reaction was also negative. On May 14 a formol-gel test was strongly positive. The next day a sternal puncture was performed and a few Leishman-Donovan bodies were found in the smear. An inguinal gland puncture, however, did not reveal any parasites in the stained film.

A course of 21 injections of "antihomaline" (a 6% lithium antimony thiomalate solution containing 16% of antimony) was given

from May 18 onwards, starting with 2 ml. I.M. on alternate days, the dose later being increased to 4 ml. Iron was given for the anaemia. The temperature swing gradually diminished in height, and became normal and remained so after the nineteenth injection (June 22). Clinically there was marked improvement, with cessation of sweats and diminution in the size of the spleen, and the white blood cells showed a steady increase. Blood counts were as follows. June 3: white cells, 1,460 per c.mm. (polymorphs 44%, lymphocytes 48%, monocytes 8%). June 13: white cells, 2,180 per c.mm. (polymorphs 29%, lymphocytes 62%, monocytes 9%). July 2: white cells, 4,660 per c.mm. (polymorphs 45%, lymphocytes 52%, monocytes 3%); red cells, 3,750,000 per c.mm.; Hb, 78%; C.I., 1.04.

Discussion

The diagnosis was that of a febrile disease with splenomegaly and leucopenia occurring in a patient returning from the Mediterranean area. Malaria was excluded by blood smears and the therapeutic test of quinine and mepacrine administration, enteric and undulant fever by the agglutination tests, and pulmonary tuberculosis by the chest skiagrams. Kala-azar was suggested strongly by the formol-gel test of Napier and confirmed by finding Leishman-Donovan bodies on sternal puncture. This was preferred to splenic puncture, which entails a risk of haemorrhage.

The long incubation period should be noted. It is stated variously to be from 1 to 6 months, but cases may occur 1½ years after exposure. As modern treatment with antimony has altered the mortality from 80% to a much lower figure the importance of early diagnosis is obvious. In 1944 the *Bulletin of War Medicine* remarked that a few proved cases of kala-azar had already been seen in this country among returning soldiers, and Thompson (1944) quoted a case occurring in an English seaman. Armstrong (1945) also described two examples of asymptomatic kala-azar in soldiers.

I am indebted to Dr. E. James, medical superintendent, for permission to publish this note, and to Mr. D. Butler for help with the laboratory investigations.

Medical Memoranda

"Purpura Provocata" in Pellagra

During the time we acted as medical officers in prisoner-of-war camps in the Netherlands East Indies a great number of cases of pellagra in all its variations were observed. The purpose of this article is to draw attention to the occurrence of purpura as a specific symptom in these cases.

One of the best-known symptoms of pellagra is erythema, which shows a predilection for parts of the body exposed to the sun. The erythema may be pronounced, but usually does not lead to purpura. On the contrary, purpura may precede it, and has been known to occur on the site of subsequent erythema. What we wish to emphasize is that the purpura should not be considered a severe form of erythema.

Purpura is a specific symptom *sui generis*. It occurred not only along the whole course of the alimentary tract but also in the skin. Only in a minority of cases was hyperaemia with dilated capillaries of the lip mucosae and gums observed. It should be mentioned that bleeding of the gums hardly ever occurred, and in these rare cases it was often doubtful if it was due to vitamin C deficiency or to pyorrhoea, etc. Purpura, often responding to administration of vitamin C, was particularly common in the early days of imprisonment. To attribute the whole illness to vitamin C deficiency because of the coincident occurrence of purpura is obviously incorrect. In our opinion the purpura we observed belongs to the pellagra group of symptoms; but this will be discussed later.

The first case occurred in an officer, thin, pale, without internal symptoms, suffering from petechiae of the lower legs. He had been "punished" the previous day by the Japanese and had to stand to attention for seven hours. We made a diagnosis of "orthostatic thrombocytopenic purpura," fully aware that this was an unsatisfactory designation. Very soon it became clear that the petechiae, particularly on the lower legs and lower arms, should be regarded as one of the initial symptoms of pellagra. The linear distribution was striking. Haemorrhagic stripes even to a length of 10 in. (25 cm.) occurred, particularly if the patient was exposed to the sun,

the linear form being due to scratching because of lice or scabies. Indeed, in all cases purpura could be produced artificially by scratching the skin with the finger or a pencil, similar to Nikolsky's bullous phenomenon in pemphigus or Köbner's phenomenon in psoriasis and lichen ruber; purpura followed, however, the same day. Exposure to the sun accelerated the phenomenon.

It should be pointed out that purpura provocata in pellagra is not identical with Rumpel-Leede's phenomenon, in which haemorrhages occur *distal* to the tourniquet. In fact, both phenomena indicate the permeability of the blood vessels and the "haemorrhagic constitution." They may even be combined—e.g., in those cases of Rumpel-Leede's phenomenon in which haemorrhages also occur *under* the tourniquet. We regard this symptom as a severe form of Rumpel-Leede's phenomenon. If doubt is expressed with regard to the diagnosis of pellagrous purpura, that of vitamin-C-deficiency purpura being preferred, we would emphasize that all patients were proved to be suffering from pellagra or (as we prefer to call it) a polydeficiency. We agree with those who consider that the use of the term "pellagra" has been too restricted in the past, and that in its widest concept it embraces a poly- (or even an omni-) deficiency, in which lack of sometimes one and sometimes another vitamin dominates the syndrome.

Adenoma of Islets of Langerhans

The following case seems to be interesting enough to merit publication.

CASE REPORT

The patient, a woman aged 59, was admitted to hospital late in the afternoon of Feb. 2, 1946. The only history was that she had sat down on the floor in the middle of a shop and refused to move.

On examination she was found to be conscious, but to all questions her only reply was: "I feel damn rotten." In the ward she was somewhat difficult to control. She was very obese, and her blood pressure was 245/140. No other abnormal signs were present. Morphine was given. By the early hours of the next morning she had quite recovered, but she could recall nothing save that she had gone out shopping that afternoon. She had had many similar attacks before and had found that they could be prevented by a cup of tea and some white bread. The attacks began in July, 1943. At that time they occurred at intervals of many months. Just before and after admission they averaged three or four a week.

During an attack her skin became cold and clammy. Her pupils were slightly dilated. Often the first warning was that she began to wink at everyone. Normally a very talkative person, she would become very quiet. Occasionally she became restless, and on one occasion threw bread crusts at some visitors. During one of these attacks her blood pressure was taken and it was found to be lower than her normal. The attacks were controlled in the early stages by giving 25-50 g. of glucose by mouth. This resulted in her recovery within five to twenty minutes. The patient was always unaware of what had happened.

Examination of the blood showed: red cells, 5,850,000; white cells, 4,200; Hb (Sahli), 105%; urea, 32 mg. per 100 ml.; Wassermann reaction, negative; B.S.R. and blood slide, N.A.D.; x-ray examination of skull, N.A.D.; urine, N.A.D.

Blood Sugar Estimations.—Feb. 7. 175 mg./100 ml. (four hours after a meal). Urine was negative, as it was throughout the glucose-tolerance curves. Feb. 12. Fasting level, 36 mg./100 ml. Feb. 13. Sugar-tolerance curve: fasting level, 32 mg./100 ml. 50 g. of glucose given; blood sugar after 1½ hours, 96 mg./100 ml.; 1 hour, 117; 1½ hours, 108; 2 hours, 32; 2½ hours, 24. During an attack the reading was 19 mg./100 ml. Feb. 15. Fasting level, 75 mg./100 ml. Feb. 28. Sugar-tolerance curve: fasting level, 31 mg./100 ml. 50 g. of glucose given; blood sugar after 1½ hours, 56 mg./100 ml.; 1 hour, 127; 1½ hours, 125; 2 hours, 80; 2½ hours, 44. The patient was quite unaware of the first blood being taken, but the 50 g. of glucose soon pulled her round.

A diagnosis of adenoma of the islets of Langerhans was made and a laparotomy was decided upon. This was done by Mr. W. J. Liddle, assisted by Dr. G. H. Moore, on March 23. A small round tumour was removed from the head of the pancreas. It was situated partly behind the duodenum, and it shelled out quite easily. A careful search was made for a possible second or third tumour but none was found. A continuous intravenous glucose-saline drip was begun before the operation. Blood was given in the theatre. An hour after her return to the ward the blood sugar was 219 mg./100 ml. The urine contained sugar the next day. The patient died on the evening of March 29. It may be added that she was conscious until shortly before death, but her breath smelt of acetone.

The tumour was 5/8 in. (1.6 cm.) in diameter; it was almost round, and firm in consistency. Section showed the presence of an adenoma of the islets of Langerhans.

I am indebted to Dr. J. R. Turner and Dr. Ison for permission to publish this report.

Reviews

THE PERIPHERAL CIRCULATION

The Peripheral Circulation in Health and Disease. A Study in Clinical Science. By Robert L. Richards, M.D. With a foreword by J. R. Learmonth, Ch.M., F.R.C.S.Ed. (Pp. 153; illustrated. 21s., plus 7d. postage.) Edinburgh: E. and S. Livingstone. 1946.

The disciples of the late Sir Thomas Lewis will recognize in this book a monograph which deserves a place with those of the master himself in the library of clinical science. Its foundations in physiology, its substance of controlled observation, and its framework of well-informed argument combine to build a structure which is both a worthy memorial to good work and a guide to those who wish to follow the scientific method in clinical investigation and practice.

A special centre for injuries of the peripheral nerves and for diseases and injuries of the peripheral blood vessels offers abundant material for clinical research. It is clear that in order to fit himself to make the best use of his opportunities the author made a close study of the literature, and one of the chief features of the book is his critical survey of the work and opinions of his predecessors and contemporaries in the field. From the pen of many a writer such a review makes tedious reading, but Dr. Richards's care in the arrangement of his references, and his attractive literary style, have given his readers enjoyment with instruction, and the book is of special value as a comprehensive account of the literature of the peripheral blood vascular system brought up to date.

A criticism of the work might be that scant attention is paid to the various methods of studying the circulation to a limb in addition to the skin temperature—the method by which nearly all the observations recorded in this book have been made. On the other hand it is plain that skin temperature records, if properly controlled and interpreted, offer the most generally useful and the most readily available method of obtaining information about the peripheral circulation. Clearly illustrated and well-documented accounts are given of the disorders of the circulation observed in obliterative arteritis and in Raynaud's disease; and a chapter of very great interest is devoted to the vascular phenomena which accompany peripheral nerve injuries. The distinction between the early warm phase and the later cold phase in a denervated area is well drawn, and many features which have been rather obscure heretofore are explained. The book ends with a masterly description of immersion foot, and the appropriate treatment for the various stages of this distressing condition is described in some detail.

Physicians and surgeons, stimulated by the researches carried out by Lewis's school, are now taking an increasing interest in the disorders of the peripheral blood vessels. While the author does not claim this book to be an extensive treatise it will prove to be most useful to the clinician in his daily practice, as well as providing him with valuable advice about where to look for further information.

ACIDOSIS

Acidosis. Clinical Aspects and Treatment with Isotonic Sodium Bicarbonate Solution. By Esben Kirk, M.D. (Pp. 222; Dan. cr. 18.) Copenhagen: Einar Munksgaard; London: William Heinemann Medical Books.

This book is a plea for the more extended use of sodium bicarbonate in isotonic solution (1.3%) in conditions of acidosis. Acidosis is defined as a condition in which plasma bicarbonate is reduced below the normal range of 22–30 milliequivalents per litre. The symptoms vary from the fatigue of mild acidosis through the dry tongue of moderate acidosis to the dyspnoea of severe acidosis, when the plasma bicarbonate is down to half.

The author refers to the introduction of intravenous injections of sodium chloride and sodium carbonate by Dr. Thomas Latta in 1831 for the treatment of cholera. Again, in 1910, the American Sellards showed the beneficial effect of intravenous sodium bicarbonate in cholera when uraemia and anuria were present. Rogers, using Sellard's treatment, reduced the mortality due to acidotic uraemia from 11.1 to 3.2%. The author's most earnest plea is for the use of isotonic sodium bicarbonate in the treatment of diabetic coma, and his evidence

that its intravenous administration leads to a rapid return of consciousness is convincing. His account would, however, be more complete if he explained why Joslin gave up the oral administration of sodium bicarbonate in precomatose diabetic cases in the year 1917. Nevertheless, the argument that combination of insulin and isotonic bicarbonate is more effective than insulin alone, and that it should always be given if the patient is moribund or if he reacts slowly to insulin alone, is strong. Most clinicians do in fact recognize the need of administering isotonic saline or glucose-saline to relieve the dehydration and to restore carbohydrate, but it is likely that sodium bicarbonate will relieve the symptoms more quickly than sodium chloride.

FROM CHILDHOOD TO MATURITY

The Psychology of Childhood to Maturity. By J. Guilfoyle Williams, B.Sc. (Pp. 324. 8s. 6d.) London: William Heinemann Medical Books. 1946.

The author has produced in reasonable compass an excellent book on normal psychology. He has not got the intimate knowledge of how things go wrong which belongs to the experienced psychiatrist, but he has read carefully and intelligently from the writings of these and so may be particularly well qualified to deal with the normal. His general approach is based on the analytic schools, but he does not slavishly adhere to any one of them and preserves a common-sense balance throughout his subject matter, which concerns psychological reactions from infancy to old age, dealing practically with child psychology, education, adolescence, sex difficulties, marriage, religion, disease, and death. He stresses the need for allowing the child to grow up in an atmosphere of wise guidance without any attempt being made to force him into mould. He rightly remarks, "The most cruel treatment of child is wanton and unjust forms of discouragement. . . . Ridicule should never be used with children and rarely with adults; it is a cruel and deeply wounding weapon." He shows his broad humanity in stressing that all sin is not sex: "Great and evil sinners are the men who destroy in others the faith they have in truth, justice, and goodness; the men who shatter some persons' irrational ideas and guides in life just to show their own powers or intelligence, but who do not replace these ideals or guides with better ones; the men who by cunning, trickery, or falsehood prey upon their fellow men by their activities in industry, commerce, the professions, or politics." The author presents an interesting theory which leaves open the possibility of survival after death, and may explain many of the well-established phenomena of clairvoyance, mysticism, and ultramaterial experiences. Altogether this is a book which will repay close study by every intelligent citizen.

PSYCHOLOGY FOR NURSES

Psychology Applied to Nursing. By Lawrence Augustus Averill, Ph.D., and Florence C. Kempf, B.S., A.M. Third edition. (\$2.50 or 12s. 6d.) London and Philadelphia: W. B. Saunders Company. 1946.

The American nurse must be a person of much greater leisure or of much greater capacity for mental work than her British sister if she can regard a textbook of psychology of 484 pages without consternation. In it, moreover, she will find at the end of each of the twenty chapters what are called "thought problems for the student," which are long examination papers, each question calling for quite long essays and probably extensive reading not only of this book but of much of the "suggested reading" to be found after the "thought problems." That so extensive a task does not, however, appal the American nurse is indicated by the fact that a third edition of this textbook has now reached us. There is no doubt whatever that this is a thoroughly sound book for its purpose, if only there was not so much of it. The authors have covered the essentials of general educational and much of social psychology in simple language which the nurse or teacher should easily understand. Quite properly there is little about the complicated material of abnormal psychology or of the theories of psychopathology. There is an admirable insistence that the nurse should teach health to her patients and to do this it is held that: (1) The nurse should have related accurate information at her immediate command. (2) She should recognize and take advantage of "teachable" moments as they occur. (3) She should have the imagination and ability to use the right approach to each

patient. (4) She should be specific in her teaching and check her patient's interpretations. (5) She should recognize her patient's limitations, mental and physical, and teach carefully in the light of these. (6) The nurse should be generous with encouragement and commendation of the effort and progress shown by each patient. (7) She should know reliable sources of reference which are expressed in the language of the lay person. (8) The nurse should herself personify positive health. Would that all our nurses could carry out these requirements. Certainly the book should find a place on the shelves of all nurses' libraries.

Notes on Books

The Circulation in the Foetus (a synopsis for students), by K. J. FRANKLIN, D.M., F.R.C.P., A. E. BARCLAY, D.M., F.R.C.P., and M. M. L. PRICHARD, M.A., is published at Oxford by Blackwell Scientific Publications, Ltd. (Price 2s. 6d.) This is a digest of the authors' large work on the same subject published in 1944. A concise account of the course of the blood flow in the mature foetal sheep, as determined by cineradiography combined with intravascular injections of radio-opaque fluids, is followed by the description of the changes which occur after birth, the functional closures of the umbilical vessels, of the ductus venosus, of the foramen ovale and of the ductus arteriosus. Some very clear photographs and six explanatory diagrams increase the value of this excellent synopsis.

Elementary Bacteriology, by JOSEPH E. and ETHELYN O. GREAVES of the Utah State Agricultural College, of which we have received the fifth edition (W. B. Saunders Company; 20s.), is not a suitable textbook for medical students; the chapters on medical bacteriology, which occupy less than half the book, are inadequate for his needs. Those on bacterial metabolism, and on the industrial aspects of the subject, may be found useful to anyone unfamiliar with these branches. The style tends towards the sensationalism usually found only in popular works on microbiology, and the text is not free from errors, mainly in spelling. Koch, were he still alive, would be astonished to hear that his pupil, Walther Hesse, who first used agar in culture media, was an American.

In *Penicillin in General Practice* Dr. J. L. HAMILTON-PATERSON has written a useful guide to penicillin therapeutics in a handy form. He outlines its principles, describes methods both of preparation and administration, and deals then with the treatment of individual conditions. The instructions given, though brief and necessarily dogmatic, are adequate and orthodox. It is doubtful whether the more prolonged and technically difficult forms of treatment described should be undertaken outside a hospital, but their inclusion makes for completeness. It has been recognized (perhaps since this book was written) that certain bacteria here described as insensitive to penicillin are not wholly so, and some of the infections caused by them can be successfully treated. The advocacy of infrequent large doses for the treatment of syphilis should perhaps be more cautious until the effect on this disease has been studied further. The book is published by Staples Press, Ltd., at 5s.

Dr. EDWARD GRIFFITH's book *Modern Marriage*, originally written in 1935, now appears in a 19th edition (Methuen and Co.; 7s. 6d.). The author has taken the opportunity of bringing his material up to date so that it may be even more useful than it has been in the past. Now that contraception is so generally accepted, and the term "birth control" is recognized as a misnomer, Dr. Griffith has omitted that term from the title of the book. He has added several new chapters and revised the old ones; in particular, the chapter on contraceptive methods has been entirely rewritten and simplified. The new material includes a chapter on mind and the emotions, and two on the subject of sterility.

The June, 1946, number in the series *Surgical Clinics of North America* (6 numbers yearly, 55s. annual subscription: W. B. Saunders Co., Ltd., Philadelphia and London) is dedicated to the Lahey Clinic, and a number of the staff discuss the clinic's work to advance colonic and rectal surgery. A masterly description of the two-stage abdomino-perineal resection of Lahey (1935) is essential reading for the many with whom it finds increasing favour in this country. The monograph—beautifully presented and illustrated—gives a comprehensive study of the techniques and results achieved by leaders in this field, and reflects credit on the surgeons and publishers of its country of origin.

The Film Committee of the Association of Scientific Workers has recently issued a pamphlet entitled *Notes on the Formation of Scientific Film Societies*. Copies can be obtained on application to the head office of the A.Sc.W. at 15, Half Moon Street, Piccadilly, W.1. The Film Committee was set up in 1938 to further the interests of the scientific documentary film, encourage the making of more such films, and sponsor the exhibition of scientific films.

Preparations and Appliances

NEEDLE FOR INTRAMUSCULAR INJECTIONS AT REGULAR INTERVALS

Dr. I. BIERER writes from Bethnal Green L.C.C. Hospital:

Since the introduction of the 3-hourly penicillin injections we have been attempting to find a method for giving injections at stated intervals without the necessity for inserting a needle on each occasion. The reason for our desire to find such a method was that in our experience it has repeatedly happened that excitable or mentally deficient patients, or a patient weakened by a prolonged or serious illness, refused further injections. Many dreaded the experience of being awakened at night and, in expectation of the next injection, did not dare to fall asleep again. After a number of experiments we are now using the needle described below, of which an illustration is given.

A needle (a) is fixed to two wings (b) and to a female record mount (c) which lies between them. Into this mount fits a male record fitting (d) which is fixed to a third wing (e). A bayonet catch (f) fixes the male fitting firmly to the female mount. The needle is perforated at the distal end, thus ensuring a better distribution of the fluid.

The whole instrument is made of stainless steel and the needle can be sharpened or replaced when desired by the firm who have made the instrument.

To insert, the needle is gripped by the three wings and inserted with a quick movement vertically into the muscle. As a result of this vertical insertion the wings can lie parallel, flush with the patient's skin, when they are easily held by two narrow strips of "elastoplast." When this has been done, in order to administer the penicillin or other drug you grip the male record fitting by the wing and withdraw it, make your injection, and replace the fitting, turning it by about 90° while doing so, so that it is caught by the bayonet catch and the wing lies parallel with the other two wings. Another small piece of elastoplast over the third wing might be necessary. According to the place of injection and the respective age and thickness of the muscles concerned, one of the following four needles can be used:

- | | |
|----------------------------|-----------------------------|
| (1) 1 inch 21 S.W.G. | (3) 1½ inch 19 S.W.G. |
| (2) 1½ 20 .. | (4) 2½ 19 .. |

It is our general practice to leave the needle unchanged and in the same position for two days, but it has been left for up to seven days without any local reaction. After its removal it should be immediately syringed through with cold water. We have found this needle convenient to use, easy to sterilize, and quite painless for the patient, who is able to lie upon it without discomfort. A non-touch technique has been used by us in its insertion, and infection has always been avoided.

The use of such a needle appears to us to be very advantageous, especially in the case of nervous patients and those seriously ill. It should be of great benefit not only in hospital but particularly in general practice where doctors are unable to attend the patient every three hours. Once the needle is in position it is not difficult for a nurse or someone else to continue the injections according to the instructions given by the doctor. It should also prove of value in the treatment of cases of eclampsia and, apart from penicillin, in the administration of other drugs.

I am much indebted to the Medical Officer of Health, Sir Allen Daley, and to Mr. W. P. Greenwood, medical superintendent of the Bethnal Green Hospital, for the facilities put at my disposal and to the nursing staff for their help. My thanks are particularly due to Mr. Regan, of Willen Brothers & Co., 44, New Cavendish St., London, W.1, who have made the needle.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY NOVEMBER 30 1946

THE CONTROL OF AIR-BORNE INFECTION

"The supply of safe clean air intra-murally," as it was described by R. Cruickshank at the meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine reported on page 831, is a good deal more difficult than corresponding reforms in the supply of water and other necessities which may act as vehicles of infection. It is indeed the greatest problem in hygiene still awaiting solution, at least in countries such as this. The encouraging trends in mortality statistics, as Cruickshank pointed out, give a false impression: morbidity figures, if we had them, would tell a different tale. Studies of the incidence of "A.R.D.," the abbreviation for acute respiratory disease which is now current in the U.S.A., have been more numerous in that country than in our own: we know that the average American has three colds a year. But common experience as well as the results of the few deliberate studies which have been made in Great Britain assure us that colds, influenza, sinusitis, and bronchitis bulk very large among diseases causing temporary incapacity for work; these together with pneumonia and specific infectious diseases involving the respiratory tract are all involved in any attempt to improve atmospheric hygiene. So much has been done and written on this subject in the past few years that an impression may have been given of great advances either already in progress or shortly to be expected. The general impression conveyed by speakers at this meeting was that a vast amount of essential information is still lacking and that any practical attempt at air disinfection must still be regarded as an experiment. Cruickshank defined two fundamental questions to which an answer is needed. First, what are the principal foci of infection: are they to be found in public transport vehicles, schools, offices, factories, or places of entertainment? There are two ways of finding an answer to this: the study of atmospheric flora by means of the slit sampler, possibly regarding *Str. viridans* as an indicator of pollution from the mouth and throat, just as *Bact. coli* is used as an indicator of faecal pollution in water; and, in the second place, study by inquiry in different community groups. The second question, equally vital in relation to any practical attempt at reform, is: How precisely are most of these infections conveyed—by droplets (direct), droplet nuclei, or dust? Two very suggestive observations in this connexion were mentioned. "Double bunking"—i.e., placing beds one above another in dormitories—has reduced the incidence of A.R.D. by 50%, which distinctly suggests that direct droplet spread is an important factor. The oiling of floors, under similar conditions, had no effect—an observation which seems to relegate dust

to a position of little importance. As another pointed out, it does not seem quite certain that all such infection is air-borne at all: infection by contact is a possibility which must not be forgotten. How many people suffering from a cold, their hands perhaps actually wet with secretion from a handkerchief will on that account refuse for their friends' and acquaintances' sake to shake hands with them?

The discussion of practical means of preventing the aerial spread of infection was focused on two problems in this connexion—that of the hospital ward where specific infection exists, and that of the meeting-place of the community at large. These are two different questions and call for different measures. So far as the hospital ward is concerned the most fully investigated proceeding and the best supported by careful quantitative studies of its effects is the oiling of fabrics to prevent the formation and diffusion of infected dust particles. A representative of the British Launderers' Research Association told the meeting that the process of oiling has been improved and cheapened: it now need cost little more than 1d. per blanket, and the new emulsifier for the oil is something we have heard of before—cetyltrimethyl ammonium bromide. Such blankets are indistinguishable from those not so treated and have an equally long, indeed not a longer, life. But opinion about the efficacy of oiling and the necessity for it, at least as a routine proceeding, was far from unanimous. Joyce Wright confessed that a repetition of her ward trials of 1943, made in another hospital in 1945, had failed to confirm the previous results. The total bacterial count in the air of the oiled ward fell as before, but the incidence of cross infection with haemolytic streptococci in children with measles, which in the previous trial had fallen from 1 to 18.6%, was unaffected. The streptococci of the 1945 study were fewer and more miscellaneous and produced no cases of otorrhoea; but whether the difference lay in them or in some other factor was unknown. Various other opinions expressed on the usefulness of oiling gave the general impression that it should be resorted to for definite indications, but perhaps not adopted as a regular procedure.

The larger problem of disinfecting air in institutions and public places generally seems to have made little practical progress. The striking success of ultra-violet light in classrooms at the Swarthmore School, Philadelphia, in preventing the spread of measles does not seem to have been repeated elsewhere. The account by R. Hare, recently returned from America, of the sceptical atmosphere at a recent conference at Detroit at which this subject was discussed was not encouraging: it appears that neither ultra-violet light nor triethylene glycol vapour has proved its worth in large-scale practical trials. A positive contribution to this study, if scarcely beyond the stage of laboratory experiment, came from O. H. Lidwell, who cautiously both prefaced and terminated his remarks by pointing out that findings with bacteria are not necessarily applicable to viruses. Pursuing their studies of air disinfection, he and R. B. Bourdillon have shown that a quite remarkable bactericidal effect is exerted in air by lactic acid. Perhaps even better is α -hydroxy α -methyl butyric

id: this has the advantage of being readily volatilized heat, or even, from a large area, in the cold, whereas stic acid has to be sprayed. These substances are rapidly ctericidal in air in very low concentration, but in order act well on bacteria in dried particles they require a gh humidity. They have been actually tested in the mass the National Institute for Medical Research, where frement slit sampler counts of atmospheric bacteria were ade during the lunch hour. Both acids reduced the rise uring this period of activity by about half, whereas the stallation of ultra-violet lamps had a comparatively slight ough appreciable effect. As Lidwell said, any such tempt to achieve practical air disinfection is still only 1 experiment. We can give no confident answer to quirers who seek some means, apart from improved ntilation or lessened overcrowding, of improving the mospere of their premises in winter.

STARVATION IN GERMANY

he undoubted gravity of the food shortage in the British one of Germany has recently been underlined in comment in both Press and Parliament. From official and unofficial accounts there emerges the picture of a people suffering from under-nourishment, apathy, and moral exhaustion—the picture of a defeated nation now reaping the tares of Nazism. The state of health in the British one is something which must be the concern of the medical profession in this country, not only because of the humane basis of the work of the doctor but also because of the risk that a physically and morally depleted Germany may be the focus of epidemics which will spread beyond its frontiers. The voice of the propagandist is usually set in an emotional key, and in the discussions of the past few weeks it has been difficult to get a clear idea of what is happening, because there seems to be as great a shortage of facts as there is of food. As Prof. Major Greenwood points out in this week's correspondence columns: "We have no statistical information, not one death rate." We therefore publish elsewhere in this issue some figures obtained from official sources which, incomplete though they are, do at least help to bring the scene into some sort of focus.

The population of the British Zone was approximately 1,500,000 in February of this year, and it is estimated now to be about 22,750,000. The matter is complicated by the entry of illegal immigrants. The population of Hamburg is approximately 1,411,000, and on November 20 there were in Hamburg hospitals 1,197 persons diagnosed as suffering from hunger oedema; in the four weeks preceding November 20, 706 cases of hunger oedema were admitted. In a survey made on July 31, of 2,200 employees in a Hamburg gasworks 90 were found to suffer from hunger oedema. What is unknown is the incidence of hunger oedema among those not admitted to hospital, and in any assessment of its incidence we should bear in mind the observation by Dr. A. P. Meiklejohn and his colleagues in a letter to the *Times* that German doctors may naturally tend to exaggerate the incidence of hunger oedema among their compatriots in the British Zone.

Weight is one index of nutrition, and in a survey of 1,200 factory workers at Mulheim in October it was found that 82.9% of the workers weighed less than 67 kg. (10 st. 8 lb. approximately), which was taken as a standard body weight. But we should note here that the average weight of British Army recruits aged 20 during the war was about 61 kg. (9 st. 10 lb.). Tuberculosis is always regarded as a pointer to the state of nutrition in a community, and the available figures do not bear out alarmist reports of the incidence of this disease in the British Zone. Deaths from tuberculosis amounted to 1,275 in June, which was the worst month for the period June–September. This may be compared with an average four-week figure for England and Wales in 1937 of 2,135, it being borne in mind that the population in this country was then approximately twice the size of the present population in the British Zone. The morbidity rate of pulmonary tuberculosis in the British Zone for the first six months of 1946 was less than it was in the German Reich in 1941 and 1942, when the state of nutrition in Germany was supposed to have been high. From January to June of this year there was in the British Zone a progressive rise in the birth rate and a progressive fall in the infant mortality rate. In January, for example, the birth rate per thousand was 9.8 and the infant mortality 136; but corresponding figures for June were 18.2 and 72. We may recall that in 1942 the infant mortality rate for Glasgow was 91, for Dublin 98, and for Belfast 92.

It is, of course, not possible to make exact comparisons between the conditions in Germany now and conditions in England and Wales at other times; nevertheless the information that is available suggests that the picture is not so black as some have painted it. But though it is grey enough to cause apprehension there is a note of optimism in the most recent reports. According to the *Times* of November 25, the ration of 1,550 calories a day for the normal consumer in the British and American Zones of Germany will be continued during the next rationing period. It is stated that the "food position in the British Zone is regarded with more hope than at any time for the past three weeks." There is the loan of 50,000 tons of wheat and flour from the American Zone; grain and potatoes are coming in from the Russian Zone as a result of the trade agreement of September 20; and the harvest in the British Zone has this year been good, threshing now being 40% ahead of last year. But the margin is narrow enough, and no one in this country will be able to feel at ease until the Germans in the British Zone are getting enough to eat and until famine oedema has disappeared.

OTITIS AND THE MASTOID

The association of chronic otitis with a compact type of mastoid bone has long been recognized, and it was rather naturally supposed that the latter was the result of the chronic inflammatory process which caused a gradual obliteration of the air cells. Schwartz was a prominent exponent of this view and stated that eburnation or sclerosis of the mastoid bone was a frequent consequence of chronic

inflammation of the middle ear, especially when suppurative. It was, however, known that this sclerotic condition of the mastoid bone existed also with a normal state of the middle ear, and this had to be explained by an inflammatory process which had long passed away in the middle ear but continued to develop in the mastoid bone. Wittmaack later wrote much on this subject and concluded that the normal condition of the mastoid bone is cellular, the system of air cells developing rapidly at an early period of growth and producing a complete pneumatization in early childhood, though a fresh formation of cells continues throughout life. Under pathological conditions—that is, otitis in infants and in children up to two years of age—according to Wittmaack, the growth of the system of air cells is either inhibited altogether or much limited. There would thus occur both in children and in adults great variations on each side of the same person from complete absence of air cells to extensive pneumatization.

Although Wittmaack's hypothesis has received a general measure of qualified assent it has never carried conviction, and the view that the system of cells continues to develop in later life has not been fully accepted. Arthur Cheate in particular, who devoted much of his life to studying the anatomy of the temporal bone, rejected the views of Wittmaack and held that the ivory, diploetic, and fully cellular formations are anatomical variations, of which the solid varieties predispose to chronic otitis. If this is so the problem of the association remains unsolved. Marcus Diamant¹ has made investigations of a clinical nature which support Cheate but still do not fully answer the question which constantly presents itself in otology. The size of the system of air cells in the mastoid bone can be estimated fairly accurately in x-ray films in the lateral projection. A close study of this question by Diamant showed that the frontal projection had a close correspondence with the lateral, so that the volume of the cellular system could be estimated quite accurately by measurement of the lateral film with a planimeter. The clinical material was drawn from patients in a fever hospital and in private practice and included 320 normal persons, 123 cases of scarlatinal otitis, 144 cases of acute otitis media, and 275 cases of chronic otitis media, the last including both central and marginal perforations of the tympanic membrane with discharge. The original number of cases was larger, as only those subjected to re-examination could be included in the final assessment. The repeated examinations showed that in early childhood the cellular system of the mastoid is on the average small and grows rapidly, so that it is essentially fully developed in females by the age of 10 years and in males by the age of 15. It does not grow any further subsequently and appears to regress after the age of 30, contrary to the opinion of Wittmaack. In acute otitis it was found that the average size of the cellular system is only three-quarters of the size of the normal and is about three times as large as that in chronic otitis. The ear with the smaller cellular system is the one more commonly attacked (69%, as against the 50% that might be expected). In chronic otitis almost all the ears have cell systems much below the normal, the average being about a quarter of the

normal size. In marginal perforations the size is less than in central perforations. If the tympanic membrane shows scar formation the cellular system is less than normal, but the system is larger than in cases which show a persistent perforation. There is thus a close correlation between the size of the cellular system and chronic otitis, and to a less extent acute otitis. On the other hand many persons with small cellular systems never contract otitis.

This elaborate work by Marcus Diamant, which has been closely checked statistically, is therefore a striking clinical confirmation of the views expressed many years ago by Arthur Cheate, but it gives no explanation of the phenomenon.

PRE-OPERATIVE DIETS

Within recent years surgeons have become increasingly aware that the nutritional state of their patients plays an important part in their ability to withstand severe operative procedures. Since it is the protein-rich tissues or body fluids which are damaged or lost, attention has naturally been focused on the protein component of the diet. Cutbertson was probably the first to point out the magnitude of the catabolic destruction of body protein which follows injury, and he has recently reviewed the principles involved and the problems of convalescence.¹ Pre-operative dietary problems have been dealt with in considerable detail by Varco.² The pre-operative ingestion of protein in adequate amount is as, or more, effective than corresponding increments made available in the post-traumatic phase. Cutbertson and Howard and their associates³ have shown in fracture cases that despite abundant food and substantial increases in the intake of protein a negative nitrogen balance exists at the height of the catabolic period, which reaches its maximum usually within the first ten days following injury or operation. Peters⁴ has reported a similar situation in acute infections. A condition of nutritional imbalance may also be present in a patient for a considerable time before operation. The operative procedure may then accentuate the degree of negative balance, as the amino acids required for the process of repair may necessitate a further breakdown of reserve protein. According to Munro^{5, 6} this latter response is conditioned by the nutritive state, and liver dysfunction may develop, particularly when the diet has been scanty.

A satisfactory nutritional preparation will extend the benefits of surgery to the type of patient who in the past has often been regarded as too poor a risk. The pre-operative steps should include not only restoration of the water and electrolyte equilibrium but so far as possible a high-protein, high-carbohydrate diet. Skim-milk powder has been shown to have many advantages as a source of protein in pre-operative diets. Diet 1 described by Varco consisted of 160 g. protein, 407 g. carbohydrate, and 18 g. fat (calorie value 2,426 with 1.6 calories per ml. of fluid diet). Diet 2 consisted of 120 g. protein, 409 g. carbohydrate, and 37 g. fat (2,446 calories and 1.6 calories per ml.). This was a less tasty diet, rendered suitable for feeding by a nasal tube. The basis of Diet 1 was strained oatmeal, skimmed milk, lactose, orange purée, pea purée, egg, and grape juice; that of Diet 2 egg, skimmed milk, skim-milk powder, and lactose. These diets were frequently given in the order Diet 1 by day and Diet 2 by night. Diet 1 is

⁶ *Brit. J. exp. Path.*, 1945, 26, 396.

id to be palatable and is given in multiple servings. Diet 2 is designed for tubal feeding and although less palatable is taken readily by mouth. Varco has given 5,000-6,000 calories to patients with ulcerative or neoplastic lesions of stomach and duodenum but little or no pyloric obstruction. Patients with partial obstruction were given limited quantities of Diet 1 by day and Diet 2 by night. From midnight to 8 a.m. during the initial days no feeding is allowed; the stomach was then evacuated by nasal tube and the quantity measured. Patients having aspirations of less than 500 ml. were continued on this regime, which should permit or even exceed 3,500 calories daily. For patients with high-grade but not complete obstruction continuous stomach drip was set up and Diet 2 given. In cases with complete pyloric obstruction the bulk of the daily calorie intake was provided by hypertonic glucose (10% in distilled water) dripped intravenously at the rate of 100 to 125 ml. per hour through a fine needle, so that 500 ml. (1,200 calories) would be infused in ten to twelve hours. Hourly rates in excess of this caused glycosuria. The calorie requirement was further met by 1,000 ml. of 10% glucose in distilled water or saline solution, as determined by electrolyte need. Protein was supplied daily in plasma. Experience has shown that it is more comfortable if a forearm vein is used. This allows a freer range of movement than does insertion into an antecubital vein. Protein digests do not as yet appear to offer a satisfactory solution to this problem owing to the large volumes required. Further, in the non-obstructive cases there is presumably adequate enzymic activity without recourse to redigestion. Diets 1 and 2 of Varco can be applied to the treatment of cases with neoplasms of the colon, sigmoid and rectum, and to burned patients. Varco has suggested that when the percentage loss in body weight is 5-10% three to five days of proper treatment are sufficient. When the loss approaches 20% ten to twelve days are necessary, and three weeks are needed when the loss approximates 5-30%.

This recent work is very suggestive, although it does not yet provide proof that such measures of nutritional readjustment can yield a margin of safety for these poor-risk patients. The clinical evidence in support of Varco's thesis is certainly worthy of consideration and confirmatory trial.

A NEW ANTIBACTERIAL COMPOUND

Recently the discovery has been announced¹ of a new synthetic compound called furacin (5-nitro 2-furaldehyde

semicarbazone) $O_2N-\text{C}_4H_2O-\text{CH}=\text{N}-\text{NHCONH}_2$ which

is actively bacteriostatic or bactericidal, and is said to be effective clinically by local application to infected wounds. It is a yellow solid only slightly soluble in water and is not unduly toxic. In a concentration of 1:20,000 to 1:200,000 it inhibits the growth of many varieties of Gram-positive and Gram-negative organisms *in vitro*. This is not a very high degree of activity, however, and it does not act *in vitro* on *Ps. pyocaneae* or on *Str. viridans*, but does have a fairly strong action on *M. tuberculosis*.

When a single oral dose is given to mice the LD50 is about 590 mg./kg., and the chief toxic symptom is hyperirritability, which may go on to convulsions. Mice were infected with 10,000 lethal doses of various bacteria, and the effect of treatment by daily oral doses of the compound was studied. In the optimum dose (150 mg./kg. daily for 3 days) furacin was fairly active against *Staph. aureus*, *Str. haemolyticus*, and two *Salmonella* organisms, but it

was ineffective against *Str. pneumoniae*. It is fairly active against *Trypanosoma equiperdum* in mice and *Treponema pallidum* in rabbits, but it has no action on *Spirochaeta recurrentis duttoni* in mice. Even the optimum dose protects only 67-70% of the mice treated for the above infections, and the explanation of this phenomenon is obscure. Larger doses increase the death rate, although 150 mg./kg. daily is considerably below the ordinary lethal dose.

The production of every new antibacterial compound is to be welcomed, and the results of clinical trials, which will soon begin, are awaited with interest. If furacin had been described 13 years ago it would have been greeted as a great discovery, but the figures suggest only a relatively low activity *in vitro* and *in vivo*. In an era of sulphonamides and penicillin a new antibiotic requires very high therapeutic efficiency or some other advantage for it to become established in clinical practice.

WOMEN IN INDUSTRY

The report of the Royal Commission on equal pay, which was published on Nov. 6, brings into prominence the opinion that female labour is less productive than male, a view widely held by employers but dissented from by three of the four women members of the Commission. This supposed inferiority of female labour is difficult if not impossible to assess accurately; it is usually attributed in part to a greater liability to ill-health in women. The B.M.A., whose policy has always been equal pay for equal work, gave evidence before the Commission stating that the contention was not valid for medical women.

The importance of investigating the health of women in industry is emphasized by a statement made by Dr. Anna Baetjer¹ to the effect that in the U.S.A. no fewer than 16 million women are expected to be gainfully employed by 1950. Their employment presents many health and personnel problems which differ from those encountered in the employment of men, partly because of the physiological differences between men and women and partly because of differences in their social backgrounds. If women are to be utilized by industry with the maximum of health and efficiency these problems must be much more fully understood than at present. To this end, Dr. Baetjer has collected a considerable mass of such information as is available, and has presented it in a very readable form with numerous references to published work. She has by no means confined her sources to American literature, but has done full justice to the investigations made in this country. She lays stress on the considerable gaps in our knowledge which her data indicate, and the monograph should prove most useful and suggestive to future investigators.

In her long section on sickness-absenteeism, Dr. Baetjer discusses the various reasons given to account for the greater sickness of women than of men. It may be due partly to women taking their aches and pains more seriously than men do, to their having more home responsibilities and duties, and to their greater indifference to adequate nutrition, but perhaps the most important factor of all relates to the proper placement of women in relation to their physical and mental capacities, and to the attitude of their supervisors. The extent of occupational diseases among women is not known, but there is some reason to believe that toxic dusts, gases, and fumes do not affect their health more than that of men. Information regarding the number of women exposed to harmful chemical substances and the extent of their exposure is very limited,

¹ Dodd, M. C., *J. Pharmacol.*, 1946, 86, 311.

¹ *Women in Industry. Their Health and Efficiency.* By Anna M. Baetjer, Sc.D. W. B. Saunders Company. 20s.

but so far as we know it is probable that occupational dermatoses are neither more nor less common among women than men, and there is no reason why normal women should be restricted any more than men from working at jobs which involve the use of toxic substances, with one exception. This relates to pregnant women, who appear to be more adversely affected than normal women. Substances such as lead have been shown to exert a specific influence leading to abortion. Also pregnancy places a limit on the ability of women to do physical work, but there is no reason why the women should not be allowed to continue on certain types of work, especially if provision is made for changes of posture during the work period. Continual sitting is no more desirable than continual standing.

An appendix to Dr. Baetjer's book records several thousand occupations known to be performed regularly by women or apparently suitable for them, with information about the normal training period required.

"ELECTRONIC BRAIN"

A good deal of very natural misunderstanding appears to have been caused by Lord Mountbatten's reference to the possibility of an "electronic brain." There are indeed few limits to the feats of discrimination and subsequent action which radio circuits can now be made to perform. But thought, in the strict sense of the word, cannot be included among their capabilities.

The distinction is illustrated by a device of another kind which is stated to be already in use by one electrical firm for the transmission of dial readings down a telephone line. To changes of less than a certain amount this machine will "pay no attention" unless they are sustained for more than a prescribed interval of time. Greater changes, on the other hand, which may be of immediate importance, will be transmitted at once and without giving time for the needle to settle down. This is judgment, if you like; but it is judgment exercised in accordance with a set of rules which have been laid down in advance by designer or operator, and which the machine itself does no more than obey. Alternatively, one may say that the machine is displaying a reflex action, the form of which has been externally determined—or shall we say conditioned?

The manner in which such instructions are given to the machine is of considerable practical importance. In the original Eniac machine, which was built for the U.S. War Department at the University of Pennsylvania, the instructions as to the arithmetical procedures to be followed are given by making a series of plug and socket, and switch, connexions by hand. In the A.C.E. (Automatic Computing Engine) which is being built by the Mathematics Division of the National Physical Laboratory punched cards will be used to give the machine all the preliminary guidance it requires. Standard sets of cards, covering different types of calculation, will be stored in a special library; and the instructions for any particular problem will be assembled from these prefabricated units, linked together possibly by any further special instructions which may be needed. Only about two minutes of the machine's time will be occupied. The second requirement, naturally, is that of speed. The A.C.E. is being designed to multiply two ten-figure numbers in two thousandths of a second. This is about half as fast again as Eniac; but when speed of working is in any case so high any improvement in this direction will be of comparatively minor importance. Thirdly, such a machine is required to "remember," and to reproduce at a given moment, any intermediate stages of the calculation which may be required of it. This is

of obvious value in very many types of computation, and it is here that A.C.E. will have its second big advantage. The "internal memory" capacity of the A.C.E. will be 75,000 decimal digits, as compared with only 200 in the Eniac machine.

As one illustration of the heavy work which A.C.E. will be able to undertake, it may be mentioned that, whereas most mathematicians would abandon as too laborious the solving of a set of simultaneous equations with even twelve unknowns, the A.C.E. will be capable of tackling fifty or even a hundred unknowns, with merely a few extra seconds in which to do the work. On account of the high speed at which it will operate, and the short time required to give it "instructions," it is thought that this one machine will be able to handle the whole of the problems which the country's research workers and mathematicians may wish to give it.

A RADIOLOGICAL PIONEER

Older radiologists will recall the attractive personality of Major C. E. S. Phillips, who died last year after serving the Royal Institution for sixteen years as secretary. The addresses given at a commemoration meeting at the Royal Institution have just been published. They were given by those who were associated with Phillips in his various activities, which included music and sketching as well as physics, and they reveal a man (in the words of Sir Hen Dale) "whom a fortunate inheritance had placed beyond the need for working for a livelihood, but who gave eagerly of his time and substance in the field of science, art, and scholarship"—the type of the true amateur which and the rapidly changing conditions of the modern world make one fears, become rarer. Phillips was a pioneer in the application of x rays to the living body. He began work on x rays in his father's laboratory early in 1896, a few months after the announcement of Röntgen's discovery and an x-ray photograph of his belonging to that period is in existence—a skiagram of the hand, taken with a Lenard tube with 35 minutes' exposure. Later he did some notable work in formulating a quantitative basis for the therapeutic use of the radiations. Dr. W. V. Mayneord recalled how Phillips during the first world war acted as physicist to the X-ray Committee of the War Office. At about the same time he became honorary physicist to the Cancer Hospital in the Fulham Road. He was thus one of the earliest of hospital physicists. In those days collaboration between clinicians and physicists was unusual, and those who have since taken up the calling of hospital physicist are fortunate to have had as almost the first of their number a man with the knowledge, insight, and charm of Phillips. One of his strong beliefs was in the unity of purpose between the doctor and the scientist in the advancement of medical radiology. In 1909-10 he was president of the Röntgen Society, and in 1930-1 he was president of its successor—the British Institute of Radiology. The latter body possesses among its treasures a set of three small radium standards which Phillips prepared in 1909. They were made in the form of three glass tubes containing in all about 0.5 mg. of radium bromide. These three standards were compared with a weighed amount of radium bromide in Rutherford's laboratory and presented by Phillips to the old Röntgen Society.

The Croonian Lectures will be given before the Royal College of Physicians of London by Dr. H. L. Marriott on Dec. 3 and 5 at 5 p.m. Subject: "Some Quantitative Considerations Regarding Depletion of Tissue Fluid and Blood Constituents."

SOME AMERICAN IDEAS ON VENEREAL DISEASE CONTROL

BY

R. R. WILLCOX, M.B., B.S.

Lieut.-Col., R.A.M.C.; Adviser in Venereology to the War Office

The main pillars of any venereal disease control programme are: (1) the seeking and controlling of nests of infection; (2) prophylaxis; (3) getting patients and their contacts under observation and treatment; and (4) ensuring that those patients remain under treatment until they are at any rate non-infectious to others. If 100% success could be obtained on all of these four points, then venereal disease as a public menace would be conquered. In order that all concerned may co-operate to this end, the aims and the methods of arriving at them must be made public, and hence education and propaganda to a greater or lesser degree are also essential.

Let us consider briefly how far we have progressed along the road in this country. So far as seeking out-nests of infection is concerned prostitution is theoretically illegal, but anyone who walks in the West End of London can see that it is far from suppressed. Furthermore, girls known to be in the "profession" are not subject by law to medical examination. Candidates for marriage are not compelled to have a premarital blood test, though most hospital clinics do one as a routine measure in the case of pregnant women. To ensure that potentially infected people receive treatment we rely on voluntary methods of persuasion, and our attempts at legislation on this are confined to Regulation 33B, which is a step in the right direction, though from the aspect of V.D. control it is but a short distance along the path. To ensure that patients remain under treatment, arrangements via almoners and other V.D. clinic workers are as good as can be devised; on the other hand, for the tracing of infected contacts we have to rely on the public spirit and social conscience of the infected patient and the perseverance of the clinic doctor.

When viewed dispassionately, we obviously have not got very far, and, as things stand at present, probably can get little farther. Unfortunately the traditional British ideas of liberty and freedom also have to include the freedom to have venereal disease and to transmit it to others. This has obstructed any attempts to obtain broader legislation. As a result the efforts of education and propaganda suffer from the same inherited traditions, and tend to be colourless and inhibited as compared with places where legislation has been enforced. From the point of view of effect, one would have thought that countries possessing the legislation would actually require less propaganda to attain the ends required than those where voluntary effort has to be relied on. In any case, the U.S.A., which has the advantages of much legislation, finds it needs quite a considerable amount of propaganda to reinforce it, and by comparison our efforts here are puny.

Legislation

The laws enforced in the U.S.A. differ from State to State. In New York, however, the Sanitary Code, the Domestic Relations Laws, and the Public Health Laws require that a licence for marriage be refused unless the application is accompanied by a certificate stating that an examination and a blood test have been done by a competent physician within the last month. The patient also has to sign a declaration that to the best of his belief he is free from venereal disease. In addition, all physicians attending pregnant women are by law required to do a blood test for syphilis; while under Article 17b of the State Public Health Law the Department of Health is empowered to compel all individuals suffering from communicable venereal disease to seek proper and sufficient treatment, and doctors are instructed to issue circulars of information to all patients with syphilis or gonorrhoea. What is more, these diseases are compulsorily notifiable to the City Health Department. Finally, all women arrested on a charge of prostitution have a compulsory medical examination, and treatment if infected. Other cities, such as Chicago, have similar laws, and most if not all of them have a Venereal Disease Control Section at the City Health Department. In these places a central registry is kept and contacts are traced and followed by letter,

registered letter, telegram, or social visit, according to local custom and expediency, and persistent defaulters are thus found when the almoners working locally at the clinics have otherwise failed.

The following is a description of the practical application of the four major items of V.D. control in New York and Chicago.

Seeking and Controlling Sources of Infection

In my visits to Washington, Baltimore, Philadelphia, New York, and Chicago, and often walking alone on the streets at night, I was never once accosted by a woman, and prostitution as such is definitely concealed. It can, however, well be argued that it is not banished, for 5,000 women are arrested on a charge of prostitution in New York State each year, but those arrested are compulsorily examined. In Chicago bar-keepers are invited to participate actively in V.D. control, and in August, 1945, over 4,000 tavern owners attended a meeting convened by the Medical Officer of Health, Dr. Bundeson. Certificates stating that hotels and bars are co-operating are issued and displayed. This co-operation really consists in ensuring that the saloon is not used as a place of assignment, and also that information is given to social workers as to the location of any of the bar-habitues if they have been notified as contacts or potential sources of infection. If a particular bar is found to be a frequent place where patients meet the source of their infection, then the hotelier is visited by a representative of the Health Department and asked to mend his ways. If he refuses he runs the risk of having his premises shut and notices like "SYPHILIS—BEWARE!" and "VENEREAL DISEASE—KEEP OUT" plastered outside the building. Co-operation is usually forthcoming.

Prophylaxis

Methods of prophylaxis have never been so actively imposed upon civilians as on military personnel. In Chicago, Service men on furlough are given a printed list of eighteen "pro" stations that have been set up in the city for their use.

Getting Patients under Treatment

This consists in bringing in all those who are reasonably expected to be infected and the tracing of contacts. Compulsory notification is an essential to this end. In Chicago this was conducted by the epidemiological section of the Chicago V.D. control programme. The very name gives the clue to the approach to the problem, and venereal disease is being tackled realistically from the epidemiological standpoint.

All patients are interviewed at the outset and, in addition to being educated concerning their condition, are persuaded to identify all possible contacts. About 2½ contacts, on an average, are found for each case of early syphilis. Rosenthal in New York quoted 36 remembered telephone numbers out of 49 exposures from one of these "victory girls" or "patriotutes." Some 4,000 reports of contacts or diagnosed cases of V.D. are dealt with in Chicago each month, so a priority list consisting of contacts of early syphilis and recent gonorrhoea is necessary. Registered letters are used in the first instance to induce notified contacts to report to the Health Department. If these fail, then a field worker is put on the job. The field workers each have their own territory and there is a special "tavern squad." In six months (January to June, 1945) some 11,500 epidemiological reports reached the epidemiological section in Chicago. Of the patients concerned 2,614, or 22.8%, were placed under treatment, while 11.5% were already receiving it; 12.8% were examined and found not infected. Just over 30% went unlocated.

All this work cannot be done without a considerable staff. The epidemiological section has its quota of the 602 workers employed on the Chicago V.D. project. The file cards are made out in quadruplicate, the carbons being attached in advance at the printers. The phonetic system of name filing is employed, the Smiths, Smythes, and Psmiths all being grouped together. Recently they have had the advantage of electric typewriters, of which the stenographers spoke very highly. The whole project here is under the V.D. Control Officer (Dr. Theodore Bauer), who in his turn is under the Medical Officer of Health, who takes a very active part in putting over the programme.

Ensuring that Patients Remain under Treatment

In the year ending June 30, 1945, some 1,094 cases of primary and secondary syphilis had been diagnosed in the Health Department V.D. clinics in Chicago. All but 23 (97.9%) received intensive treatment in the 200-bedded Chicago Intensive Treatment Centre, a hospital used solely for this purpose. This centre has been a forerunner of rapid syphilis therapy with intensive arsenic, with fever, and latterly with penicillin, by themselves or in combination. The average stay in hospital is ten days and all treatment is free. Attractive meals are served cafeteria style, and no visitors or incoming telephone calls are permitted. The wards, however, carry public telephone booths for outgoing calls, so that the patient is isolated only so far as he or she wishes to be. This innovation is a real boon for patients and could with advantage be copied in Britain, as, apart from the benefit to patients, it is time-saving for the nursing staff, who otherwise often undertake such small jobs. The hospital was opened in 1942, and early in the New Year of 1945 it treated its ten-thousandth patient.

While they are in hospital patients are supplied with magazines, games, and puzzles. Recreation hours are organized in the hall, equipped with a piano, a juke box, library, and canteen. Handicraft classes are offered as diversional therapy, and films are shown four nights weekly—two for men and two for women. It cannot be denied that in Chicago the vast majority of syphilis cases diagnosed are getting full and adequate treatment.

The gonorrhoea cases attend the clinics as out-patients. The Chicago Municipal V.D. Clinic takes the bulk of these, and may well be the most-used V.D. clinic in the world, some 1,300 passing through its doors each day. Over twenty persons of both sexes can be dealt with simultaneously. This clinic is in a converted school, and the actual buildings are not anything marvellous. Its clientele are black and white of all grades of society. The main waiting-room is like a station on a bank holiday, while in the treatment room a small corps of doctors are dealing with patients as fast as they can go in the twelve centrally operated cubicles. In 1944 some 23,500 cases of venereal disease were treated in this clinic alone. In its first year of operation—1918—only 870 were treated. All cases of syphilis are referred for treatment at the Intensive Treatment Centre, as also are patients with penile sore and lymphogranuloma inguinale, for diagnosis. The gonorrhoea cases are treated on the spot, using the one injection technique of penicillin in oil-beeswax. As with syphilis, all diagnosed cases of gonorrhoea are receiving their full treatment.

For the tracing of cases for follow-up, social workers are used by the individual clinics. From the epidemiological standpoint the majority of patients with syphilis or gonorrhoea have actually already received the full amount of treatment necessary to cure them before leaving the hospital or clinic. However, a careful follow-up, especially of the syphilis patients, is necessary so that reliable data on the success of the various treatment schedules used may be obtained. As a result of letters, telephone calls, telegrams, and field visits, some 70% of the first 3,000 early syphilis cases treated in the intensive treatment centre at Chicago are still under observation.

From the foregoing it is obvious that everything possible is being done to ensure that infected persons are brought under observation, and a very high standard of success is obtained in seeing that cases, once found, do receive the necessary treatment, thus rendering them non-infectious.

Propaganda

Propaganda regarding venereal diseases is used to reinforce the main points already mentioned. However, before any propaganda can be used the actual diseases have to be "mentionable." The same influence is noticeable in this country, and the initials V.D. usually feature largely on any propaganda placards. I do not think we have yet succeeded in making V.D. a topic that can be discussed freely everywhere without embarrassment. Certainly the mild efforts on the radio, while admitted at the time, have not reached the level of a weekly feature. America has not yet completely succeeded either, but the words are being forced into the vocabularies of the inhabitants whether they like it or not. They have argued that "T.B." and "B.O.," as terms, are socially acceptable, and

as the latter has so become solely by frequent advertising, by the same process, V.D. can too. Hence at present much propaganda still has to be wasted in bringing the real subject on the agenda for discussion, and the motives, such as advising treatment centres, urging blood tests, or discouraging promiscuity, are bound up with the general advertising of the subject. Furthermore, there is no shortage of paper in the U.S.A.

In Chicago the trams and buses are an obvious medium for the display of propaganda posters. The first one used was "Do you know, THOUSANDS have V.D. and don't know if you are one of them?" At the foot, in smaller print, was the address of the Chicago Health Department: "Ring Ran 80 Ext. V.D." This has now been changed to "Don't be Ostrich—Face the Facts—V.D."—a slogan which was also found on leaflets in New York. Window cards for barbershops, hotel-keepers, and "co-operators" are also available and doubtless were used during the first flood of enthusiasm though I do not remember seeing them being used anywhere during my visit. Matches, too, are employed. The Harlem Social Hygiene Council distribute in New York book match coloured black with "V.D." in large red letters on the cover (the initial selling motif again). In Chicago, where perhaps they consider that the initials are now accepted, a more modest book match is used with a yellow cover bearing the words "FIND OUT . . ." and an arrow pointing inside to a list of addresses of the municipal clinics. Matches are given away free, by tobacconists in the United States, and in Chicago many were done to induce drug stores and other establishments to buy propaganda varieties. Over a million have already been issued, and a further million are on order.

A strong Chicago placard contained a black-and-white picture of a lady of the streets and was inscribed, "Easy to get—V.D." Another leaflet available in a New York health centre, showing a very photogenic six-months-old baby, was inscribed, "Our children need never know the sorrow of SYPHILIS." A further leaflet in the same centre, headed, "What you don't know CAN hurt you," contained the following story:

"Arguing Al was scared of syphilis. Al would face any man in an argument or fight, but he could not face going to his doctor and finding out what ailed him. You know how some people feel . . . 'What I don't know won't hurt me.' That was Al. The sore that was worrying him went away he said: 'Aw, I wasn't syphilis,' and he put the whole thing out of his mind. Fifteen years later syphilis put him in a wheel-chair for the rest of his life. From then on his wife and kids had to shift for themselves and for him, too. The pay-off was this: Al had lost out to syphilis. The doctor could have cured him, if Al had seen him when the first came. . . ."

This more direct approach obviates any repetition of the story of the lady Chicagoan who thought V.D. meant vital deficiency.

Over 600 workers are employed to carry out Chicago's programme, and everything is done to make them understand the whole picture. Originally issued bi-monthly, but now published quarterly, is a small periodical entitled *V.D. Topics*, written solely round the work. It carries, too, a "scandal-sheet closure" with information about weddings and other social activities of the workers and even the doctors themselves. At least one occasion the entire staff has been allowed time to attend a short course given by other members on their particular aspects. This even included the staging of a series of skits showing, among other things, imaginary conversations with difficult wives, and the tavern squad at work.

A new type of advertising has been tried recently with movie juke box which alternates entertainment reels with V.D. control messages. The complete show lasts ten minutes, can be operated free by pressing a button. It was first used at the large municipal clinic to educate and relieve the tide of waiting out-patients, and, in order not to interrupt the show, a blackboard was improvised to call the patients when treatment was due. Latterly it has been fulfilling a number of two-week engagements in the various billiards saloons in the city. Medical Officer of Health gives luncheon addresses, which are carried by newspapers, and the radio is used for talks. On a broader basis, the American Social Hygiene Council as part of its widespread activity holds conventions on Feb. 7, which is National Social Hygiene Day.

To the British mind the first reaction to some of these ideas is one of surprise mingled with amusement. On consideration, however, it is readily perceived that it is all the logical pursuance of an accepted line of thought. Venereal disease must be reduced and stamped out. To do this, legislation is introduced, and to make it watertight the fullest publicity is given. It is both logical and realistic; but its results are disappointing. The number of gonorrhoea patients in Chicago V.D. clinics climbed from 892 in August, 1944, to 1,685 in August, 1945. This was partly attributed to the popularity of penicillin. However, the numbers of new cases of venereal disease are still rising. In New York, too, they are on the increase. It is said, though, that the rate of increase is less when compared with that during and after the war of 1914-18, and also that much of the increase is apparent owing to the greater and ever-increasing efficiency in tracing contacts and getting infected persons under treatment. When the peak is reached it will be interesting to see to what level the final figures attain as a result of the realistic programmes that are afoot. Meanwhile we must never lose sight of the trenchant observation of Stokes, as quoted by Rosenthal:

"Venereal disease dissemination takes place in the period between infection and the institution of treatment control. It is not the patient under treatment who spreads disease, but the promiscuous individual before and after treatment. In other words, we must move against promiscuity rather than, or in addition to, disease."

[Note.—The views expressed in this paper are my own personal opinions and not necessarily those of any official body with which I may be associated.]

LEAGUE OF RED CROSS SOCIETIES

At the 19th meeting of the board of governors of the League of Red Cross Societies, held at Oxford, recommendations of the advisory health committee of the League were presented by its chairman, Dr. Fred Routley. The part which the national Red Cross Societies might play in rehabilitation and also in the blood transfusion service was discussed. It was agreed that the rehabilitation and resettlement of the disabled is a form of humanitarian service in which Red Cross Societies in every country ought to take part in every way possible. It was recognized that rehabilitation is a continuous process, beginning in hospital and extending throughout convalescence, that it is an individual process, requiring adaptation to the need of each patient, and that it is a vocational process, related to the patient's future means of employment. It was agreed that members of Red Cross Societies should be prepared to take an active part in the work of rehabilitation by assisting the trained staff in hospitals and rehabilitation centres and by helping disabled persons in their own homes. Special reference was made to the rehabilitation of the tuberculous.

On the question of blood transfusion it was considered desirable that a Red Cross Society should not pay for any blood supplied to it by a donor, but that it should, by continuous publicity, point out to all citizens the great value of transfusion and their obligation in safeguarding the lives of others by ensuring an adequate supply of blood. Other recommendations were that in countries in which an adequate blood transfusion service does not exist Red Cross Societies should investigate the possibilities of establishing such a service under their own direction, and that there should be uniformity in the colours of the cards used to denote blood donor groups so as to facilitate international working; thus green might be chosen for universal donors (O), red for the AB group, and yellow and white for the A and B groups respectively. It was also recommended that in view of the part played by some Red Cross Societies in the control of epidemic and endemic disease an international meeting of experts in infectious diseases should be convened.

BRITISH ZONE IN GERMANY
NUTRITION AND DISEASE

While public comment on the health of Germans has been voluminous in the last few weeks, a dearth of published vital statistics has rendered much of it a matter of speculation. We therefore reproduce below three Tables (I-III) from the journal sponsored by the British Control Commission, the *British Zone Review* (Oct. 12, 1946, 1, 28). The figures are those officially accepted by the Public Health Department of the Control Commission.

TABLE I.—Vital Statistics for German Reich

Year	Birth Rate per 1,000 per annum	Death Rate per 1,000 per annum	Infant Mortality per 1,000 Live Births per annum
1938	19.6	11.6	60
1939	20.4	12.3	61
1940	20	12.7	Not available
1941	18.6	12.0	" "
1942	14.9	12.1	" "
1943	16	12.2	" "
1944	Complete figures not available		
1945			

TABLE II.—Vital Statistics for British Zone

1946	Birth Rate per 1,000 per annum	Death Rate per 1,000 per annum	Infant Mortality per 1,000 Live Births per annum
Jan.	9.8	15.4	136
Feb.	11.7	14.3	109
March	13.7	16.1	109
April	16.1	15.1	89
May	17.9	14.1	82
June	18.2	10.9	72

TABLE III.—Morbidity from Infectious Diseases: Incidence per 1,000 Population per Annum

	German Reich				British Zone	
	1938	1939	1941	1942	Last 6 Months 1945	First 6 Months 1946
Diphtheria ..	2.2	2.2	2.28	3.12	2.7	2.19
Scarlet fever ..	1.68	1.93	3.1	4.46	0.49	0.3
Pulmonary T.B. ..	0.89	0.91	1.31	1.41	0.73	1.01
Other T.B. ..	—	0.082	0.17	0.19	0.9	0.16
Cerebrospinal fever ..	0.027	0.078	0.053	0.031	0.01	0.01
Polio-myelitis ..	0.085	0.053	0.059	0.044	0.02	0.002
Typhoid ..	0.043	0.05	0.036	0.18	0.78	0.42
Paratyphoid ..	0.047	0.048	0.054	0.068	0.17	0.03
Dysentery ..	0.078	0.079	0.11	0.17	0.25	0.07

The difficulties in arriving at accurate figures are acknowledged by the Control Commission, not the least of them being the assessment of the population at risk. At the end of February of this year the population of the British Zone was approximately 21,500,000; on Aug. 31 it was 22,691,463; and at present it is about 22,750,000. About 5,000 illegal immigrants are entering the British Zone every week from the east, most of them in "very bad condition." In addition a small number of refugees are legally admitted.

It will be seen from Table II that the infant mortality rate is higher than it should be. Nevertheless, the figures for April, May, and June, 1946, compare favourably with those in many towns in the United Kingdom. In 1942 the infant mortality rate in South Shields, for example, was 83, in Sunderland 81, and in Merthyr Tydfil 82; and one need go no farther back than 1910 to find rates throughout the United Kingdom as high as the highest German figures.

Nutrition Surveys

Sample weighings of persons from all classes of the German population in the British Zone are carried out fortnightly, and the opinion held by the Control Commission is that there has recently been a slight, continuous, overall improvement in nutrition throughout the British Zone, except in Hamburg and Kiel, where the situation has got worse.

A survey of 1,200 factory workers was made at Mulheim in October, 1946. A standard body weight of 67 kg. (10 st. 9 lb. approx.) was taken, and it was found that 17.1% of workers weighed more than this, 82.9% less.

Communicable Diseases

Figures compiled by the Control Commission in Germany are shown in Table IV. They are for four-week periods in the months indicated, and record the number of cases notified in those periods. The dashes mean either that there were no cases in that period or that the figure is not available.

TABLE IV.—Communicable Diseases Return: 4-week Periods

	June		July		August		September	
	Cases	Deaths	Cases	Deaths	Cases	Deaths	Cases	Deaths
Anthrax	—	—	—	—	—	—	—	—
Diphtheria ..	6,344	169	5,502	195	5,998	187	7,815	224

Whooping-cough ..	—	—	—	—	3,281	16	4,302	22

The figures for diphtheria are high—about twice those obtaining in England before the war. The incidence of dysentery, on the other hand, compares favourably with that of wartime England. Scarlet fever is less prevalent than in England during the autumns of 1943 and 1944.

Deaths from all forms of tuberculosis are not as excessive as individual reports in the daily press would suggest. The population of England and Wales is approximately twice that of the British Zone in Germany. In England and Wales there were 27,754 deaths from all forms of tuberculosis in 1937 and 25,143 in 1942. One-thirteenth of these figures will provide a comparison between deaths from tuberculosis in the British Zone now with those in England and Wales in 1937 and 1942. The highest German figure—1,275, for June—can be compared with the average 4-week figure for England and Wales in 1937 and 1942—namely, 2,135 and 1,934 respectively for a population of approximately twice the size. Though for many reasons the comparison cannot be an exact one, the figures nevertheless indicate that tuberculosis in the British Zone now is neither more nor less serious than it was in England and Wales so short a time ago as 1942.

An instruction was issued to Regions in August of this year that in future all *active* as opposed to *open* cases of pulmonary tuberculosis were to be notified. A point to be noted, too, is that proved tuberculous cases receive extra food rations. It is admitted that the figures in Table IV are not as accurate as, for example, those obtainable from the British population; but there is no reason to suppose that they are widely inaccurate.

Hunger Oedema

The incidence of hunger (or famine) oedema is exceedingly difficult to determine. A survey on July 31, 1946, of 2,200 employees at a Hamburg gasworks revealed 90 cases of hunger oedema. A report on hospital admissions as received in London on Nov. 20 is shown in Table V.

TABLE V.—Hunger Oedema: Report of Nov. 20, 1946

Town	Approximate Population	In Hospital	Number Admitted in last 4 weeks
Berlin (British Sector)	609,688	177	111
Hanover	300,000	62	26
Münster	70,000	3	9
Düsseldorf ..	300,000	118	18
Hamburg	1,411,000	1,197	706

Hospital Accommodation

Finally we append some details of hospital beds available and occupied by the German population in the British Zone as on Oct. 1, 1946.

Beds occupied ..	218,332	Beds for tuberculosis cases ..	23
Beds available ..	258,710	Per 1,000 population ..	1
Per 1,000 population ..	11.2		

REGIONAL HOSPITAL BOARDS
PROPOSED AREAS

The Ministry of Health sent the letter which is printed below to a number of organizations, inviting their observations on the areas provisionally defined for the Regional Hospital Boards to be set up under the National Health Service Act.

Ministry of Health,
Whitehall, S.W.1.
Nov. 15, 1946

National Health Service Act

SIR.—I am directed by the Minister of Health to refer Section 11 of the National Health Service Act which requires him by order to determine the areas for which Regional Hospital Boards shall administer hospital and specialist services under the Act on his behalf. By virtue of subsection (1) of that Section, the areas must so far as practicable be such that hospital and specialist services of the area can conveniently be associated with a university having a medical school; and subsection (2) requires the Minister in determining the areas to consult the bodies and organizations which appear to him to be concerned.

Accordingly I enclose for the benefit of any observations statement setting out the provisional view of the Minister as to the areas appropriate for the purpose, having regard to the considerations stated in Section 11 of the Act and to the needs of the hospital and specialist services. In drawing up that statement, the Minister has also had in mind the following additional considerations to which your attention is drawn:

(1) The size and extent of the areas must be determined primarily by reference to their purpose, which is to provide an area adapted rather for the planning, co-ordination, and provision of hospital and specialist services than for the control and management of hospitals. The latter task will, as stated in Section 12(2) of the Act, be the function of the Hospital Management Committees. It follows that the areas can and should be comparatively large in population, and such that each has a natural university medical centre as its focal point. In considering this aspect of the problem the Minister has had regard to the recommendations contained in the Hospital Survey Reports published during the past 10 years.

(2) In certain Regional Board areas geographical or other circumstances appear to render it necessary that for part of the area there should be set up a Regional Committee of Board with delegated powers and its own offices. The Minister has in mind such areas as Devon and Cornwall, Hampshire, Dorset, and Isle of Wight; North Lancashire and South Westmorland; and Cumberland and North Westmorland.

(3) The boundaries of Regional Board areas need not and will not prevent the free passage of patients from one area to another. Indeed in some instances at the outset Regional Boards will become responsible for hospitals, etc., in the area which have belonged to and served communities in other areas, and which must continue to do so.

(4) It appears to the Minister that wherever possible the boundaries of the Regional Board areas should coincide with those of local health authorities, in order to secure the maximum of administrative efficiency. Except where other considerations must in his view clearly prevail, the proposed boundaries accordingly follow those of counties and county boroughs.

(5) In some instances it appears that other important factors (e.g., association of the services with the appropriate

medical schools, grouping of related hospitals under the same Regional Board) make it essential to cross local health authority boundaries in defining the boundaries of Regional Board areas. Here again the Minister has sought wherever possible to ensure that the proposed boundaries shall coincide with those of boroughs or county districts.

In view of the clear necessity for allowing Regional Hospital Boards as much time as possible to perform the many preliminary duties which must be completed before Part II of the Act takes effect, it is a matter of some urgency to lay before Parliament the orders defining their areas, so that the Boards themselves may be constituted in the very near future. I am therefore to request that the Minister may receive any observations on the proposed boundaries at the earliest possible date, and in any case not later than Dec. 15.

A similar letter has been addressed to each university with a medical school, and each separate university medical school, the three Royal Medical Colleges and the British Medical Association; the British Hospitals Association and its Area Committees in England and Wales; the King Edward's Hospital Fund for London; the Nuffield Provincial Hospitals Trust; the Association of Voluntary Teaching Hospitals; the County Councils Association; the Association of Municipal Corporations; the Mental Hospitals Association; every local health authority; the Federation of British Industries; and the Trades Union Congress. A further letter with regard to the constitution of Regional Boards will be sent in due course to the bodies concerned.—I am, Sir,

Your obedient Servant.

J. E. PATER

The following are the areas to be included in the proposed areas of Regional Hospital Boards, listed according to the appropriate University Centre.

Newcastle

Counties of Cumberland, Northumberland, and Durham.
County Boroughs of Carlisle; Newcastle-upon-Tyne and Tynemouth; Darlington, Gateshead, South Shields, Sunderland, and West Hartlepool.

County of Westmorland (Appleby B. and North Westmorland R.D.).

County of York, N. Riding (Middlesbrough C.B.; Boroughs of Redcar, Richmond, and Thornaby-on-Tees; U.Ds. of Eston, Guisborough, Loftus, Northallerton, Saltburn and Marske, and Skelton and Brotton; and R.Ds. of Croft, Northallerton, Reeth, Richmond, Startforth, and Stokesley).

Leeds

County of York, E. Riding.
County of York, N. Riding (except area in Newcastle Region).
County of York, W. Riding (except area in Sheffield Region).
County Boroughs of Kingston-upon-Hull; York; Bradford, Dewsbury, Halifax, Huddersfield, Leeds, and Wakefield.

Sheffield

Counties of Derby (except area in Manchester Region), Leicester (except Hinckley U.D.), Lincoln (Parts of Holland, Parts of Kesteven, except area in Cambridge Region), and Parts of Lindsey, Nottingham, and Rutland (except Ketton R.D.).

County Boroughs of Derby; Leicester; Grimsby and Lincoln; Nottingham.

County of York, W. Riding (C.Bs. of Barnsley, Doncaster, Rotherham, and Sheffield; Borough of Goole; U.Ds. of Adwick-le-Street, Beniley with Arksey, Conisborough, Cudworth, Darfield, Darton, Dearne, Dodworth, Hoyland Nether, Maltby, Mexborough, Penistone, Rawmarsh, Royston, Stocksbridge, Swinton, Tickhill, Wath-upon-Deane, Wombwell, and Worsborough; R.Ds. of Doncaster, Goole, Kiveton Park, Penistone, Rotherham, Thorne, and Wortley).

County of Stafford (Burton-on-Trent C.B. and Tutbury R.D.).

Cambridge

Counties of Bedford (except area in N.W. London Region), Cambridge, Huntingdon, Isle of Ely, Norfolk, Soke of Peterborough, Suffolk East, and Suffolk West.

County Boroughs of Great Yarmouth and Norwich; Ipswich.

County of Essex (Saffron Walden B. and R.D.).

County of Herts (Royston U.D.).

County of Lincoln (Parts of Kesteven) (Stamford B., Bourne U.D., South Kesteven R.D.).

County of Rutland (Ketton R.D.).

London

(i) *North-West*.—Counties of Bedford (Luton B. and R.D., Dunstable B., Leighton Buzzard U.D.), Bucks (Boroughs of Chepping Wycombe and Slough; U.Ds. of Beaconsfield, Chesham, Eton, and Marlow; R.D. of Amersham, Eton, and Wycombe).

Berks (Boroughs of Maidenhead and New Windsor; R.Ds. of Cookham, Easthampstead, and Windsor).

Herts (except areas in Cambridge and N.E. London Regions).

Middlesex (except area in N.E. London Region).

London (Hammersmith (north of Goldhawk Road and Stamford Brook Road), Hampstead, Holborn, Islington, Kensington (north of Holland Park Avenue, Notting Hill Gate, and Bayswater Road), Paddington (north of Bayswater Road), St. Marylebone, St. Pancras, Westminster (north-east of Park Lane, north of Constitution Hill, Birdcage Walk, Great George Street, and Bridge Street)).

(ii) *North-East*.—Counties of Essex (except area in Cambridge Region); Herts (Hertford B., U.Ds. of Bishop's Stortford, Cheshunt, Hoddesdon, Sawbridgeworth, Ware; R.Ds. of Braughing, Hertford, and Ware); Middlesex (Edmonton B., Tottenham B., Enfield U.D.); London (Bethnal Green, City, Finsbury, Hackney, Poplar, Shoreditch, Stepney, Stoke Newington).

County Boroughs of East Ham, Southend-on-Sea, and West Ham.

(iii) *South-East*.—Counties of Kent and East Sussex; London (Bermondsey, Camberwell, Deptford, Greenwich, Lambeth (east of Kennington Park Road, Brixton Road, and Brixton Hill), Lewisham, Southwark, Woolwich).

County Boroughs of Brighton, Canterbury, Eastbourne, and Hastings.

(iv) *South-West*.—Counties of Surrey and West Sussex; Hampshire, Isle of Wight, Dorset (except area in Bristol Region), Wilts (Boroughs of Salisbury and Wilton; R.Ds. of Amesbury, Mere and Tisbury, and Salisbury and Wilton); London (Battersea, Chelsea, Fulham, Hammersmith (south of Goldhawk Road and Stamford Brook Road), Kensington (south of Holland Park Avenue, Notting Hill Gate, and Bayswater Road), Lambeth (west of Kennington Park Road, Brixton Road, and Brixton Hill), Paddington (south of Bayswater Road), Wandsworth, Westminster (south-west of Park Lane, south of Constitution Hill, Birdcage Walk, Great George Street, and Bridge Street)).

County Boroughs of Bournemouth, Croydon, Portsmouth, and Southampton.

Oxford

Counties of Berkshire (except area in N.W. London Region), Buckingham (except area in N.W. London Region), Northampton, and Oxford.

County Boroughs of Northampton, Oxford, and Reading.

Bristol

Counties of Cornwall, Devon, Gloucester, Somerset, and Wilts (except area in S.W. London Region).

County of Dorset (Boroughs of Bridport and Lyme Regis; Sherborne U.D.; R.Ds. of Bournemouth, Bridport, and Sherborne); Isles of Scilly.

County Boroughs of Bath, Bristol, Exeter, Gloucester, and Plymouth.

Cardiff

The whole of Wales and Monmouth.

Birmingham

Counties of Hereford, Leicester (Hinckley U.D.), Salop, Stafford (except Burton-on-Trent C.B. and Tutbury R.D.), Warwick, and Worcester.

County Boroughs of Birmingham, Coventry, Dudley, Smethwick, Stoke-on-Trent, Walsall, West Bromwich, Wolverhampton, and Worcester.

Manchester

Counties of Cheshire (except area in Liverpool Region), Lancashire (except area in Liverpool Region), and Westmorland (except area in Newcastle Region).

County of Derby (Boroughs of Buxton and Glossop, U.D.s. of New Mills and Whaley Bridge, and R.D. of Chapel-en-le-Frith).

County Boroughs of Barrow-in-Furness, Blackburn, Blackpool, Bolton, Burnley, Bury, Manchester, Oldham, Preston, Rochdale, Salford, and Stockport.

Liverpool

County of Cheshire (C.B.s. of Birkenhead, Chester, and Wallasey; Boroughs of Bebington, Congleton, and Crewe; U.D.s. of Alsager, Ellesmere Port, Hoyle, Hooton, Knutsford, Lymm, Middlewich, Nantwich, Neston, Northwich, Runcorn, Sandbach, Winsford, and Wirral; R.D.s. of Bucklow, Chester, Congleton, Nantwich, Northwich, Runcorn, and Tarvin).

County of Lancashire (C.B.s. of Bootle, Liverpool, St. Helens, Southport, Warrington, and Wigan; Boroughs of Crosby and Widnes; U.D.s. of Abram, Ashton-in-Makerfield, Aspull, Billinge and Winstanley, Formby, Golbourne, Haydock, Hindley, Huyton with Roby, Ince-in-Makerfield, Litherland, Newton-le-Willows, Ormskirk, Orrell, Prescott, Rainford, Skelmersdale, Standish with Langtree, and Upholland; R.D.s. of Warrington, West Lancashire, Whiston, and Wigan).

ROYAL VICTORIA HOSPITAL, BELFAST

The growing concern felt by the Board of Management over the financial position of this large voluntary hospital was the subject recently of editorials and articles in the press of Northern Ireland. Though in the preceding three years the hospital's income had exceeded expenditure there remained at the end of 1945 an accumulative adverse balance on revenue account of approximately £25,000. In the first six months of 1946 expenditure has exceeded income by £17,800 and the net of gifts, endowments, bequests, etc., received during this period has amounted only to £9,000. Over the same period of year the amount received was £15,000. At recent meetings of the Board of Management the causes of this increased expenditure and decline of the hospital's income were discussed and it was pointed out that increased expenditure was inevitable in view of the rise in nurses' salaries and in wages generally and because of the increased price of commodities. Against this there had been a decline in the working people's contribution attributable to the fact that more people were employed last year mainly on war work. These reasons only partly explained the situation, however. More important still was the misunderstanding that had arisen in the minds of the general public over the increase in National Health contributions from 1s. 1d. to 2s. Many people apparently had the impression that the extra money was being levied with the object of benefiting the hospitals. It was unfortunately only too true also that the prospect of the Government taking over all assets of the hospital had affected donations and bequests so that the number of these has shown a tendency to fall off. A serious financial crisis was, therefore, likely to arise until the policy of the Government in respect of the inauguration of the National Health Service was made clear. In the past the hospital had relied for over 50% of its income on the activities of the Working Men's Committee and their supporters, whose admirable efforts in the past had been largely responsible for the sound financial situation of the hospital to date. At a recent meeting a resolution was unanimously adopted that the working people's contributions should be increased by 1d., and a drive is being instituted to effect this through the co-operation of the city's large industrial concerns and the employees in them.

The annual report of the hospital for the year 1945 showed that there were 9,616 admissions to the wards distributed thus: 3,120 to the medical wards, 4,918 to the surgical wards, 1,642

to the gynaecological wards, and 536 to the eye, ear, nose, and throat department. The average daily number of beds occupied was 498 and the average stay of each patient in hospital was 18.8 days. There were 545 deaths during the year, and of these patients 172 died within 48 hours of admission. Excluding those who were moribund at the time of admission the death rate works out at under 4%. In the out-patient department the number of new patients was 57,066—a high figure and one which reflected the important part played by the hospital in the health services of not only the City of Belfast, but the province as a whole. The hospital had been one of the centres taking part in the clinical trials of penicillin on behalf of the Medical Research Council of Great Britain, and special interest was attached to the results achieved in subacute bacterial endocarditis, the results of which have been incorporated in a report made to the M.R.C.

THE NURSING PROBLEM

Sir ERNEST ROCK CARLING gave an address at the nurses' prize giving and annual reunion at the Southend Municipal Hospital, Rochford, Essex, on Oct. 19. He suggested that with impending changes in the health service of the country, when the basis of the whole hospital and sickness services was being examined it was necessary to look once again with fresh eyes at the nursing service, without which the rest could not function. The whole nursing problem should be reconsidered in the light of changed conceptions regarding hospitals themselves. The present generation realized that hospitals were only one link in the chain of agencies dealing with a social problem; that it was not enough to bring acute illness to an end; that recovery of full health and efficiency until return to occupation was in a sense more important, because without it the results of curative measures were dissipated or thrown away. Sir Ernest suggested that the nursing problem likewise was one which covered the home, the clinic, the school, the factory, the whole environment of the healthy; that all these departments of service were equally honourable and that they could not thrive in isolation.

The Need for Interchange

The nurse in a mental hospital must not be left there for ever; the district nurse must not be so cut off from hospital that her professional knowledge rusted. There must be interchange, seconding, pooling of experience; and that would not come about so long as hospitals jealously limited their own trained nurses to their own institutions. The parochialism about hospitals, at any rate about some voluntary hospitals, in regard to their nurses, though commendable in the 18th and 19th centuries, was deplorable in the 20th. In a few months' time regional boards would be appointed and would proceed to set up local management committees for groups of hospitals. They would have hospitals of every kind under their care—general, special, mental, infectious disease, tuberculosis, and long-stay hospitals, cottage hospitals, and so on. Could it be imagined that the nursing service any more than the accident service or the maternity service, or the mental service, would remain isolated in single institutions? Could the full education of the nurse exist without transference to hospitals of many types? Medical students would certainly broaden the basis of their education, and so would nurses.

Broadening the Field of Recruitment

The enormous demands for nursing upon the total woman-power of the country could not be met from the yearly quota of girls getting the School Certificate; there were not enough of them. That meant a broadening of the field of recruits, whether one liked it or not, and in his opinion examination standards were a false guide to the women wanted. Sir Ernest Rock Carling outlined a scheme to meet the future situation. This would rest on a basic training in the art and craft of nursing of two years' duration, which everyone must take, and at the end there should be entitlement to the name "nurse," not "assistant nurse." This should be open to all girls without any difficult educational test. There should then be a further term of 1½ to 2½ years for all whose educational attainments were adequate. In it some degree of specialization might begin early, so that in the end they might attain the title of nursing sister (surgical), (children), (obstetric), (tuberculosis), (mental), (school), and so on. From the very best of this class should be chosen those who were to graduate from a staff college. In every region or group of regions there should be a staff college for the supply of sisters-in-charge of units or teams, for sister-tutors, for wardens, and for matrons. It should be allied to the university.

MEDICAL INSURANCE AGENCY

At the Trocadero Restaurant, on Nov. 22, the Medical Insurance Agency gave a dinner to some sixty representatives of the medical and insurance worlds. The toast of the "Medical Insurance Agency" was proposed by Mr. E. A. J. Heath, manager and actuary of the Medical Sickness, Annuity, and Life Assurance Society. In replying, Sir Francis Fraser described the many links between insurance and medical practice. The toast of "Our Guests" was proposed by Mr. A. N. Dixon, the manager of the M.I.A., who has recently returned from service with the R.A.F. Mr. Dixon welcomed each of the many guests. His toast was responded to by Mr. W. W. Williamson, general manager and actuary of the Norwich Union Life Insurance Society. Mr. Williamson picked up a remark made by Sir Francis Fraser to the effect that medicine had done much to increase the average age of the population, and suggested that in the experience of his Society this increase seemed to affect particularly its annuitants.

In the course of the dinner it was announced that in the first ten months of this year the M.I.A. had secured proposals amounting to well over £2,000,000. Since the foundation of the Agency in 1907 doctors themselves have benefited to the extent of £175,000, and just over £75,000 has been handed over to medical charities and particularly to Epsom College and the Royal Medical Benevolent Fund.

APPOINTMENTS IN IRAQ

The following staff is urgently required by the Government of Iraq: Professors of obstetrics and gynaecology, diseases of the ear, nose, and throat, ophthalmology, bacteriology, pathology, chemical pathology, physics; and director of the parasitological laboratory. The appointments will be for three years in the first instance, but a contract for a shorter period may be considered. The salary is at the rate of Iraq dinars 150 a month, and there is in addition a cost-of-living allowance, at present I.D.24 a month (I.D.1=£1). Free first-class passages are provided. Application should be made to the Crown Agents for the Colonies, 4, Millbank, London, S.W.1.

Reports of Societies

CONTROL OF AIR-BORNE INFECTIONS

A meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine was held on Nov. 22, with Dr. H. J. PARISH in the chair, for a discussion on modern methods in the control of air-borne infections.

Dr. ROBERT CRUICKSHANK, in some introductory remarks, defined air-borne infection as infection by inhalation. There were only two strictly air-borne means of spread—dust, and what Wells had called "droplet nuclei." He believed that these two might prove more important in the spread of infection than the direct droplet. One way of assessing their relative importance would be to eliminate one of the variables and observe the effect. The task was to supply clean, safe air intra-murally without danger or discomfort to the community, a task which was more difficult and complex than the supply of clean, safe milk or water.

It was true that the mortality rate for air-distributed infections had markedly declined, but there was no appreciable decline in morbidity except in the few diseases, such as small-pox and diphtheria, which could be controlled by prophylactic vaccination. Respiratory infections such as colds, catarrhs, influenza, sinusitis, and bronchitis still seemed to be as prevalent as they were a century or more ago. In the U.S.A. it had been shown that individuals in different cross-sections of the community averaged three colds a year. In this country few data were available, though certain local surveys had been made. He referred, among others, to Smith's observations in Glasgow in a poor-class community which showed that two-thirds of all the cases reporting sick within a year were cases of acute respiratory disease, and more than half the working time lost was due to this cause. In boarding schools 40-50% of sickness absenteeism was due to nasopharyngeal infections and influenza. A recent analysis made by the Wartime Social

Survey, taking random samples of households, had shown an incidence of over 40% of all illness as due to acute respiratory infections. In order to find out which were the important "community foci" of infection—e.g., railway carriages and other public transport, schools including nursery schools and nurseries, badly ventilated offices, overcrowded factories, cinemas and other places of entertainment, modern methods for bacterial sampling of the air could be utilized. Standards for clean air should be established, using either the total bacterial content or an indicator organism like *Str. viridans*. New "portable" methods for measuring ventilation were also being devised.

We were still largely ignorant of the relative importance of droplets, dust, and droplet nuclei in the spread of different respiratory infections. One method of assessment was to eliminate one of the variables and note the effect. He mentioned the classical work of Alison Glover on the effect of bed spacing in the control of cerebrospinal meningitis and a recent American study on the value of "double-bunking" in reducing the epidemic spread of acute respiratory disease. Dust-control measures were apparently effective in controlling streptococcal throat infections but not virus infections of the upper respiratory tract. Ultra-violet light in schools seemed to prevent the spread of such specific fevers as measles, mumps, and chickenpox but not the common cold.

Streptococcal Cross-infections

Dr. JOYCE WRIGHT gave a description of the control of streptococcal cross-infection in the measles ward at the North-Western Hospital, London, and later at the Eastern Hospital. The object of the investigation was to discover whether the control of dust would reduce the number of haemolytic streptococci in the ordinary air. The method employed was to apply dust-laying oils to the bedclothes and to other contents of the ward. In the first results there was a 91% reduction in the total bacteria and a 98% reduction in haemolytic streptococci in the air of the oiled ward as compared with the controlled unoled ward. The incidence of cross-infection also declined steeply. The results encouraged the belief that dust was an important vehicle for streptococci in wards, and that oiling was successful in its control. When the investigation was repeated the difference, for some reason, was less marked, perhaps because it was made at a different time of year; but she thought it quite possible that in a future measles epidemic oiling would prove satisfactory in the reduction of streptococcal cross-infection.

Mr. F. COURTNEY HARWOOD (Director of Research, British Launderers' Research Association) gave an account of suitable emulsifiers for the oiling of hospital bedclothes, a procedure which he and others had described in detail in the *British Medical Journal* for May 6, 1944. The emulsifiers used were the kation-active "fisanol C" and the anion-active "teepol," but the use of other commercial emulsifiers was possible. It was necessary, along with the oiling, to maintain good laundry practice. He mentioned one well-known hospital which, after oiling its bedclothes for two years, complained that the oiled blankets were not lasting as long as the unoled, and were unpleasant in various ways, but on investigation it was found that the blankets had never been washed since the oiling began; they had been oiled at intervals and given two rinsings in plain water after each oiling. The addition of oil to fabrics in no way impoverished them if proper precautions were taken. No signs of dermatitis had been noticed among patients or nursing staff after the oiling of the blankets. Cross-infection since the adoption of the oiling technique had been much diminished. The cost of the materials used in the preparation had been 3½d. per blanket, but the cost was being brought down to the level of about 1½d.

Use of Chemical Agents

Dr. O. H. LIDWELL, a collaborator with Dr. R. B. Bourdillon at the National Institute for Medical Research, spoke of the use of chemical agents for the purpose of reducing the content of infective material in the air. He said that all the methods were still in the experimental stage, and none of them could be said to be entirely efficient or without difficulty in application. There were at present no practicable methods of assess-

ing the degree of contamination of the air by virus infections; all the work had had to be done on bacterial infections, yet from the point of view of cross-infections those caused by viruses were more important and widespread. He described the experiments with hydrochloric, lactic, and other acids. Lactic acid had been investigated in more detail than any other agent. It became very much less effective at the lower relative humidities, and at below 40% humidity it was almost if not quite ineffective. Its practical drawbacks were that it was not very easy to distribute in the air of a room, and at concentrations only a little above the working level it became irritant. Glycol seemed to show promise, but as yet there was not much experience of it. The phenolic substances were disappointing in this field. Resorcinol was effective in certain situations, but difficult to maintain in concentration in the air. Ultra-violet light had been mainly up to the present an American experiment, but its suitability for schools was being tried out in this country. Its effect upon the total dust-borne organisms was small but definite.

Dr. M. MITMAN described some experiments in aerial disinfection at Joyce Green Hospital by means of a germicidal mist, resorcinol. The results were not as promising as was hoped. No untoward effect on patients was noted, but discoloration of walls and ceilings took place. The simplicity of the method, however, justified its further investigation.

Major CUNLIFFE illustrated some experiments in the dust control of surgical wards by the oiling of bedclothes. The number of streptococci was reduced, and there was a significant fall in the incidence of streptococcal infections. Dr. J. L. BURN, who also showed illustrations of some experiments, pointed out the importance of disinfection of the floor. Under modern educational methods it was on the floor that many young children carried out their work and play.

General Discussion

Dr. O. C. STALLYBRASS said that two of the greatest recent advances in epidemiology had been the work on viruses and the work on air-borne infection. Droplets were the major medium of infection in temperate climates, and second only to insect bites in hot climates. During a measles epidemic the oiling of blankets was undertaken at his hospital at Liverpool, with complete satisfaction to the matron and nurses. Dr. STANLEY BANKS said that during the last six months, since his return from war service, he had been impressed by the almost complete absence of cross-infection in the scarlet-fever wards of his hospital. He hoped that in the zeal for these new methods the older methods would not be forgotten—ventilation, bed-spacing, chemoprophylaxis, and chemotherapy.

Dr. ALLAN MCFARLAN pleaded for a distinction between merely bacteriological cross-infection and clinical cross-infection in which there was definite illness. He hoped there would be no wholesale oiling of bedclothes. With present commercial methods there would always be a temptation to market these preparations and put them forward as essential to all hospitals. It was worth while seeing whether the law of diminishing returns did not apply here.

Dr. J. M. ALSTON said that entirely air-borne infection within a ward, when all the secondary cases could be shown to be the result of such infection, was a comparatively limited thing. From a practical point of view there could be no doubt that contact had a good deal to do with certain infections. He thought there was a case for a more adequate toilet of the nose, and suggested the impregnation of handkerchiefs. Dr. WILLIAM GUNN spoke appreciatively of Dr. Joyce Wright's work at the North-Western Hospital. He was not in favour of the oiling of blankets as a matter of invariable routine. He thought it was a valuable method to be kept in reserve for use when necessity arose.

American Experience

Prof. RONALD HARE said that in May last he attended a meeting of the Society of American Bacteriologists at Detroit. Very extensive ultra-violet light installations were demonstrated, but the results did not appear to be commensurate with the trouble and expense. Those who favoured triethylene glycol had an almost equally large installation, but here again the results did not seem to justify the outlay. Striking results were

obtained when oil was used on the bedding, but he could remember what the infection rate was. Much work had to be done in different centres before one ward could be compared with another or one hospital with another. It might be possible to prevent bacterial infections with various methods of ventilation and house-cleaning in sleeping quarters, but it would be practically impossible to prevent virus infections. This was brought vividly before him when he was in Canada. The Mackenzie River in the North-west was frozen in winter, and in the spring a steamer made its way along the newly thawed river to the Arctic. One year the boat, when it left the Great Slave Lake, carried an influenza infection, and from that point onwards all down the river, according to the reports from Mounted Police posts, the whole population—natives, white and half-breeds—were infected with influenza. That could hardly be said to be due to blankets or anything like that. What was possible in the case of bacterial infections would almost certainly not be possible for virus ones.

Dr. CRUICKSHANK, in reply, reminded the meeting that the old antidotes still maintained their importance—good ventilation which would overcome the effect of crowding; daylight, which had a bactericidal value (whether fluorescent lighting would help also in that respect was not yet established, but he thought it might); and humidity, which did help to destroy both bacteria and viruses.

THORACIC SURGERY

At a meeting held at the Royal Devon and Exeter Hospital on Oct. 17 of the Devon and Exeter Medico-Chirurgical Society Prof. MILNES WALKER paid tribute to the work of Mr. HARKEN, of the U.S.A.M.C., on the surgery of war wounds of the heart, and described a case in which a bullet had slipped through the tricuspid valve on attempts at removal before a third operation was finally successful. He discussed the surgery of intrathoracic goitre and thymectomy for myasthenia gravis, with special reference to thyrotoxic myopathy and suggested that some of the cases benefiting from thymectomy might have done so because of the partial thyroidectomy performed at the same time. He then described the surgery of the oesophageal pouch, achalasia of the cardia, and carcinoma of the oesophagus, stressing the value of early diagnosis of carcinoma by means of the oesophagoscope and x rays, and the necessity for team work between surgeon, physicist, radiologist, and pathologist.

X-ray Therapy Disappointing

Mr. BELSEY said that in his experience the results of x-ray treatment of carcinoma of the oesophagus as studied by the oesophagoscope were not impressive. Some combined attempts by the surgeon and the radiotherapist on the primary growth might hold out better prospects. Dr. WROTH agreed that encouraging early results obtained by x-ray therapy had proved disappointing. Dr. FULLER mentioned that a barium swallow did not reveal an early case and that a suspicious case of dysphagia might need following up before the diagnosis could be confirmed. He described the unfortunate sequelae of cancer he had seen—e.g., heavy burning of the skin from x rays, death from mediastinitis, or early metastasis after operation. Dr. Wroth agreed that a barium swallow could not exclude a carcinoma of the oesophagus in its early stages.

Strictures of Oesophagus

Mr. ETHERINGTON WILSON asked if aspiration of an intrathoracic goitre was not a great technical aid in operation and whether suture of the fascia surrounding an oesophageal pouch to the stump after excision was not an added safeguard. Mr. HOOD mentioned the common occurrence of oesophageal strictures in Russia due to children drinking sulphuric acid used to dry the air between double windows. Mr. Belsey mentioned the occurrence of multiple oesophageal strictures and the difficulty of outlining a lower unsuspected one by barium swallow. He thought that the oesophagoscope had great advantages in that respect.

Prof. Milnes Walker in reply agreed that the oesophagoscope was of more value than a barium swallow. He preferred

There is strong evidence that 'Ethamolin' exerts a lasting beneficial effect in the sclerosing treatment of varicose veins. Treatment is effected with a minimum of discomfort to the patient, and the total amount injected is normally less than 6 cc. 'Ethamolin,' an aqueous solution of 5 per cent. monoethanolamine oleate with 2 per cent. benzyl alcohol, produces a firm adherent thrombus. There is no fear of sloughing in the event of accidental leakage from the vein. Being powerfully bactericidal, 'Ethamolin' reduces the risk of infection to a minimum. With the growing recognition of 'Ethamolin' as a safe and efficient sclerosing agent, the need for operative treatment of varicose veins becomes increasingly rare.

ETHAMOLIN

BRAND OF MONOETHANOLAMINE OLEATE
2 cc. ampoules, boxes of 6 and 100. Bottles 15 cc. and 30 cc.

AXO LABORATORIES LTD., GREENFORD, MIDDLESEX. BYRn 3434

For Oral Medication

KERFOOTS

Proflavine Lozenges

enable the affected tissues to be bathed in a naturally buffered antiseptic solution.

Each contains Proflavine Sulphate 3 mg.
In bottles of 36 and 500

KERFOOTS

Sulphanilamide Lozenges

are of special value in throat affections due to local streptococcal infection.

Each contains Sulphanilamide gr. 1
In bottles of 50 and 500

Vitamins in diseases of the muscular system

The following are suggestions for the application of vitamin therapy in certain diseases of the muscular system. Other conditions of the muscular system were dealt with in a similar form in the last issue of this Journal.

Condition	Indications	Therapeutic Agents
FIBROSITIS	The condition responds to wheat germ oil applied locally as an inunction and taken by mouth.	FERTILOL One 3 mg. capsule daily for prolonged periods possibly with Fertiloil Cream applied locally.
HYPO-TONIA pink disease	The association of hypotonia with loss of weight and digestive disturbances calls for high doses of both B ₁ and B ₆ .	VITAMIN B₁ , (Aneurin Hydrochloride) Vitamins Ltd. 10 mg. daily by mouth or injection. PYRIDOXIN , Vitamins Ltd. 10 mg. daily by mouth or 50 mg. by injection. Later BEMAX can be given as part of the diet.

Further particulars of the various vitamin products are obtainable on request from:

Vitamins  Limited

(Dept. B.X K.I Upper Mall, London, W.6)

Is a sterile
Sulphonamide
pack possible?

Yes, and here is the answer. Not only do 'STERUCID AMPOULES' contain 'Albucid' (sulphacetamide) or 'Albucid' Soluble (sodium sulphacetamide) as a finely divided, absolutely sterile powder, ready for immediate use; the ampoules themselves can easily be sterilised externally. In sulphonamide therapy where large surfaces or cavities have to be treated, 'Albucid' may be preferred to the more soluble 'Albucid' Soluble, since it minimises the risk of too rapid absorption of a large dose of the drug.

STERUCID AMPOULES containing
5 grams Sterile Albucid Powder.

STERUCID AMPOULES containing 5
grams Sterile Albucid Soluble Powder.

Fully descriptive literature will be sent on request.

BRITISH SCHERING LIMITED
167-169 GL. Portland Street, London, W.1

PENICILLIN...

in Ophthalmology

Applying Penicillin eye drops

ACUTE superficial bacterial infections of the eyes respond rapidly to treatment with Penicillin in the form of eye drops, and also as an ointment. Excellent results have been obtained in the treatment of styes, blepharitis, conjunctivitis, hypopyon ulcers and ophthalmia neonatorum.

A copy of our booklet entitled "Penicillin Therapy" will gladly be sent upon request

AUSTIN EDWARDS LTD., FULBOURNE ROAD,
WALTHAMSTOW, LONDON, E.17.

The patient has a name for it **"BILIOUSNESS"**

"Doctor, I think I am bilious. I have no appetite. My bowels don't move as they should."

The term "Biliousness" has well served to designate congestion of the liver for generations.

Whatever name it goes by, Veracolate can take its measure therapeutically. Veracolate is designed to exert its remedial influence upon the two principal pathognostic symptoms: biliary deficiency and constipation. Veracolate stimulates choleric and cholagogue action by the introduction of bile salts combining sodium taurocholate and glycocholate in the proportion in which they occur in normal bile.

Composition: Sodium Taurocholate and Sodium Glycocholate, with Cascara, Phenolphthalein, and Capsicum.

PRESCRIBE...

'BEPLEX' CAPSULES

*B Complex
in a convenient form*

When Vitamin deficiency results in symptoms of fatigue, anorexia and loss of weight, 'Beplex' capsules may be prescribed with benefit.

Three capsules will provide: Thiamine Hydrochloride 1,000 gamma, Riboflavin 800 gamma, Nicotinamide, 10,000 gamma, Pyridoxine gamma, Pantothenic Acid 13 gamma.

Supplied in bottle of 50 Capsules.

JOHN WYETH & BROTHER LIMITED (SOLE DISTRIBUTORS FOR PETROLAGAR LABORATORIES), CLIFTON HOUSE, EUSTON ROAD, LONDON, N.W.

gave a drain down to the stump of an oesophageal pouch rather than suture the fascia, because a fistula, usually transient, sometimes formed. Aspirating a retrosternal goitre sometimes helped, but an intratracheal anaesthetic, as Sauerbruch advocated, was even more important as a means of avoiding splitting the sternum. He had seen a case of two separate carcinomata of the oesophagus separated by one and a half inches of healthy oesophagus.

DIFFICULT LABOUR IN MULTIGRAVIDAE

At a meeting of the North of England Obstetrical and Gynaecological Society held at Liverpool on Oct. 4, papers were read by Drs. BRYAN WILLIAMS, A. A. GEMMELL, and C. P. BRENTNALL.

Dr. WILLIAMS, discussing "some factors causing difficult labour in multigravidae," took as his criterion an individual who had had at least eight previous children born normally, and did not include, as an abnormality, a low forceps delivery with her previous child, an unaccountable stillbirth, antepartum haemorrhage, or any other complication not directly associated with the actual birth of the child. After eliminating such conditions he was left with twenty-three cases in which difficulty was experienced in a subsequent labour. On the whole he found that the cause of the difficult labour was either an unusually large child, some degree of contraction of the pelvis, or both. He proved that there was a marked tendency for the children of later pregnancies to be larger than their older siblings, and described how in many cases the mother's pelvis became definitely contracted. This pelvic contraction, probably due to minor osteo-malacic changes in the bones, was acquired after the birth of her first or second child. This was confirmed by the experience of observers in countries such as China where similar changes in the bones were well marked and very prevalent, and no doubt the cause was hypovitaminosis.

Micturition after Vaginal Plastic Operations

Dr. A. A. GEMMELL recommended the instillation of 1 fl. oz. (28 ml.) of 0.5% "mercurochrome" into the bladder directly after operations such as those for prolapse, and described his results in sixty-three cases treated by this method and compared them with fifty cases treated without the instillation. Of the first group 9.5% needed catheterization compared with 72% in the other group. He was strongly of the opinion that this was an excellent method of dealing with this post-operative complication, and he felt that it was due to the irritant action of the solution.

Techniques for Colporrhaphy

Dr. C. P. BRENTNALL summarized the history of the colporrhaphy operation in Manchester, pointed out the different techniques of Fothergill and of Donald, and gave his reasons for advocating the former. This paper was regarded as of the utmost importance in settling the controversy which has raged around the names of these two great men.

USE AND ABUSE OF SULPHONAMIDES

The meeting of the Liverpool Medical Institution, held on Oct. 24, was in the form of a symposium under the chairmanship of Dr. G. F. RAWDON-SMITH.

Several viewpoints on the importance of sulphonamides in prophylaxis; their indiscriminate use in infections, particularly whether diagnosis before treatment aiming at precision or treatment before diagnosis aiming at expediency should be the rule; the use of subclinical doses in undiagnosed cases; the rarity of toxic effects if adequate nursing, fluid intake, and rest in bed were insisted upon; and early fall of temperature as insufficient evidence of recovery from the pneumonic process—were advanced by the principal speakers. Drs. DOUGLAS RIDING, C. A. CLARKE, and A. O. ROSS, followed by Drs. R. W. BROOKFIELD, F. GLYN-HUGHES, LENNOX JOHNSTON, G. WILLIAMSON, and G. Y. YARDUMIAN. The sudden arrest of a cerebrospinal meningitis epidemic by prophylactic treatment of the 75,000 inhabitants of a Mexican town, and the very reduced incidence of sensitization-dermatitis in England in contrast with the Tropics, were among the interesting points made.

Vital Statistics in Western Europe

SIR,—Down to 1939 any private citizen interested in the vital statistics of Western Europe had no difficulty in satisfying his curiosity. It is true newspapers hardly ever printed any information because foreign vital statistics had no, and our own very little, news value; but official publications were available in many libraries. Since 1939 there has been no information.

It is now more than a year since part of Germany passed under British control, and I recall official intimations in your advertisement columns that the services of persons familiar with, among other things, vital statistics were needed. No doubt these were obtained, and it would be a poor compliment to the staff of the occupying power to doubt whether gross death rates and index figures of mortality at ages under one year are being prepared. But, so far as I know, no vital statistical information has been published.

I shall not ask your space for a dissertation on the value of death rates as sanitary indicators, and I have no doubt our colleagues in the Military Government of Germany use them. What I do plead is that these data should be made available to private citizens. As things are, we (by "we" I mean the large number of medical men and of students of social phenomena who have an elementary knowledge of vital statistics) cannot judge the significance of passing events. At irregular intervals we read that the food position in Germany is more, or less, grave; that expert A takes a serious view of the position or that expert B finds matters not too bad. Then a "crisis" develops; Mr. Victor Gollancz and the Bishop of Chichester take the field in the *Times*; more sensational papers talk about riots, military precautions, and so forth. But we have no statistical information, not one death rate.

If regularly, say once a month or even once a quarter, the medical press were able to publish a summary of current vital statistics in the British zone, we should be able to form some judgment. I do not need to be told that in a devastated country ruled by foreigners vital statistics of the standard set by our own General Register Office cannot be had; the best should not be made the enemy of the good or even tolerable. What I do fear is that official reticence, a dread of giving information which might be misused, is responsible for the complete public ignorance which prevails.—I am, etc.,

Loughon.

MAJOR GREENWOOD.

The Plebiscite

SIR,—Having completed my plebiscite form in the negative with a reservation, after careful and prolonged consideration, I am wondering if my own difficulty in deciding which way to vote is peculiar to myself or has been experienced by others. While I am in agreement with the objections of the Council of the B.M.A. on one point I find myself agreeing with the Minister on all the remainder. As I understand it, the purpose of refusing to negotiate with the Minister is to show him that the present Act is unacceptable to us. The one point which is unacceptable to me—i.e., the basic salary—is so vital to my mind that it compels me to insert "No" on my ballot paper.

This referendum will give the Negotiating Committee a clear-cut decision; but it may also give them quite the wrong impression as to what there is in the Act which makes the majority of the voters feel that it would not produce an efficient service for the patient if put into operation as it now stands. They will also be unable to enlighten the Minister on this point. A further referendum by means of which we could indicate which of the official B.M.A. objections are actually our own would serve to show the strength of feeling on the various principles involved. I, for one, cannot see my way to give any undertaking not to enter the service by giving a negative vote on my ballot paper, while the referendum gives me no opportunity to indicate which of the principles I am prepared to treat as vital. The dust of political battle seems to

me to obscure the real issue. Surely what we really want is a health service so framed as to enable us to do our best for our patients and to get the best in the way of investigation, advice, and treatment for them when we cannot give it ourselves. An efficient service from the patients' view-point will be bound to be a satisfactory service from the doctors' angle.

I submit that, though the present referendum may "bring the Minister to heel" and give rise to "victory celebrations" of varying kinds, a more detailed ballot such as I have indicated would make it far more constructive and might assist the Minister and our legislators to provide for our patients what the bulk of them would appear to need badly—namely, an efficient insurance service in which we as their doctors can give them of our best.—I am, etc.,

Bournemouth.

ROBERT RISK.

SIR,—Dr. Dain, at the end of his Exeter address, referring to the plebiscite, says: "Here we have an opportunity of saying that we will not take part in a service that does not concede our principles. . . . We should be infinitely stronger in talking about terms and conditions if we had first by our own efforts secured the acceptance of our principles." Yet we are being asked to vote on whether we shall negotiate on "terms and conditions" *before* we vote on acceptance of "principles." This is certainly putting the cart before the horse, and I am afraid some doctors may think that by saying "Yes" to the plebiscite they are in fact voting for negotiating with the Minister on "principles." Whereas, of course, the fact is that the Minister flatly refuses to negotiate on our "principles" and even the House of Lords has been unable to secure the acceptance of our fundamental "principles." The Bill is now on the Statute Book in opposition to the overwhelming vote of the representative body of the profession.

We should have been asked whether we are willing or not to work the National Health Service Act as it now stands on the Statute Book. If the answer is "No," then the question of terms and conditions does not arise. If the answer is "Yes," then the negotiating of terms and conditions will logically follow. However, it is too late to change the question, but I think the next issue of the *Journal* should contain prominent emphasis on the points above mentioned, for it is most important that there should be as few "Yes" answers as possible. Ruin stares us in the face.—I am, etc.,

Ilford.

N. BEATTIE.

SIR,—Reflection on the plebiscite question fills me with grave foreboding, for without a strongly negative lead I consider it a blunder of the first magnitude. The question which seems to invite the answer "Yes" surely assumes that the Minister is prepared to enter into discussion with our Negotiating Committee. Is this not a dangerous assumption to make when time and time again we have been informed by our representatives that the Minister has continually refused to negotiate and has remained consistently uncompromising? In the absence of any indication that the leopard has changed its spots I submit that the question is misleading.

Accepting the question as it stands, how is the reply to be interpreted? I can well imagine that a resounding affirmative vote would bring joy to the Minister's heart and that he would regard it as a signal to proceed on his dictatorial way. On the other hand, can anyone doubt but that a strongly preponderating negative reply would cause an intense shock to his nervous system and alter his outlook? This brings me to the paradoxical conclusion that anyone who desires the Negotiating Committee to enter into discussions with the Minister on the Regulations authorized by the National Health Service Act must answer "No."—I am, etc.,

Birmingham.

ALASDAIR MCI. SMITH.

SIR,—I have been in general practice now for just on twenty years, and since 1930 have been in a working-class practice in Southampton. In 1939 I found myself in command of a Territorial hygiene company, and as such was graded as a specialist in military hygiene, and spent the next six years in preventive medicine and had much to do with advising on

accommodation, food supplies, and how to make full use of the ration in order to ensure that each individual absorbed the full calorie value of the food. One of my greatest difficulties was trying to make the theories of the experts work in practice, and as far as food was concerned I regret to say that largely failed.

On my release from the Army I returned to general practice in October, 1945, imbued with the spirit of preventive medicine and realizing that in the past I and other G.P.s gave too little thought and action to this branch of medicine, for on the G.P. can do any real work in this sphere. What do I find? I find my waiting-room full of patients with minor ailments, all preventable—coughs and colds; dermatitis or furunculosis, lumbago and sciatica, and neurosis. On visiting my patients I found overcrowding such as I have never experienced before (eight-nine adults living in a council house, with a few children thrown in), food a little better than starvation level, with the supply of dairy produce below the safety line.

Meantime, statisticians publish figures to show that the health of the nation is excellent (there have been no major epidemics), industry calls for greater effort and condemns absenteeism. The conditions cited above never reach the statistician, but there can be no reduction of absenteeism until they are eliminated and this can only be done by a virile housing programme and a considerable, urgent increase in the supply of dairy produce—milk, cream, butter, and eggs.

Being convinced of this from *practical* experience, I am doing what I can in the treatment of my patients to supply the deficiency, to get them fit in the minimum time and back to industry; in this I am greatly handicapped by the fact that the number of priorities is strictly limited to an inadequate number of diseases. At this stage the Minister of Food "cracks the whip," making irresponsible accusations of "lax" certification, and the tragedy of the position is that doctors rush in print to *excuse* themselves. Dr. A. K. Young (Nov. 16, p. 75) alone has the courage to be forthright and tell the Minister that his patients' interest comes first.

If the general practitioner to-day is afraid to face the fact which only he can see in the homes of the people, and is told by a Minister, surrounded by his experts and theorists when he shall issue milk certificates, what will the position be when the new State medical service is in being? We have asked this week-end to consider the future of medicine; although I have long been an advocate of State medicine, there is much in the present Act which is detrimental to medical practice. But, if only for the reason stated above, I must answer "No" to the plebiscite.—I am, etc.,

Southampton.

JAMES G. McDOWELL.

SIR,—I sincerely hope that every member of the medical profession will read or has read Dr. Alfred Cox's letter in your *Journal* (Nov. 9, p. 707). I know of several doctors who were going to answer "Yes" to the plebiscite because of the statement in the plebiscite, "A decision to enter upon discussions does not involve a decision to enter the Service." This is obviously true. On the other hand, the answer "Yes" is in fact condoning the Act and is a victory for Mr. Aneurin Bevan. When this was explained in detail they changed their answer to "No."

Let there be no confusion at this time when we are fighting for the life or death of the profession. Unless we wish to become full-time Civil Servants we must answer "No" to the plebiscite.—I am, etc.,

Mansfield.

HUGH TATE.

SIR,—Dr. Dain's admirable address at Exeter has clearly stated the problem of the National Health Service Act. All the good points in it and more can be part of a new Bill really serving Health. The present Act is unmasked as a tremendous political attempt to enslave us all—profession, hospitals, and people alike—under State control. The time for negotiations is past; they have failed. Our duty is clear. Let us all in the name of justice and liberty answer the plebiscite at once, and answer "No."—I am, etc.,

Winchester.

SYBIL TREMELLEN.

SIR,—I should welcome the opportunity to add my appreciation of the most admirable communication from Dr. Alfred Cox (Nov. 9, p. 707) emphasizing the need for retaining the freedom of disposal of practice goodwill plus the necessity for remuneration to be placed on a capitation basis. This commendable letter needs to be read in conjunction with your leading article in the same issue, wherein it is clearly shown that the postulation of a basic salary emanates from the urgency of obtaining satisfactory certification. May I be permitted to comment that no perplexity need now exist in completing the form of plebiscite and in offering an immediate rejection to legislation which promotes financial instability and then shoves the onus of its own responsibilities in the matter.—I am, etc.,

Tipton.

L. H. EUNSON.

SIR,—Can Mr. Bevan's Act, even after negotiations, be altered to agree with our principles? The answer is "No." The answer to the plebiscite question is, therefore, "No."—I am, etc.,

Glasgow.

A. L. COWAN.

SIR,—I hope it is not too late to appeal to every member of the medical profession—be he or she on the staff of a teaching or a non-teaching hospital, a medical officer of health, or a general practitioner—in replying to the question submitted by the British Medical Association on the subject of the National Health Service Act, to consider the interests of the profession as a whole, and sectional interests only in that framework. Whatever decision we make, we should aim as far as possible at unity.—I am, etc.,

London, W.S.

HAROLD H. SANGUINETTI.

SIR,—If we say "Yes," we are still free to say "No." If we say "No," we are no longer free to say "Yes." Carry on, Freedom.—I am, etc.,

Leeds.

W. S. MACDONALD.

SIR,—In the issue of the *Journal* for Nov. 9 there are two contributions which I would urge every member of my profession to study and ponder and study again. The first is the letter on the plebiscite by my old friend and companion-in-arms, Alfred Cox. Like him I suppose I must consider myself an old soldier, but like him I scent the battle from afar. Perhaps those who are, or may soon be, in the thick of the fray may not be unwilling to consider the views of those who, in their time, fought and won many a pitched battle on behalf of their profession. I have italicized "and won" because this brings me to the other contribution—namely, the address by Field-Marshal Viscount Montgomery on "Morale in Battle."

Dr. Cox mentioned the waverers who plead that it (the enslavement of the medical profession) is "inevitable." I believe that if anything can bring failure in the coming struggle it will be this attitude of defeat. Lord Montgomery gives his recipe for morale, and as one of the contributory factors he mentions success. Now in my talks with members of my profession, both personal and at Divisional meetings, one thing has surprised me more than any other—namely, that the younger members are unaware of, and the older members seem to have forgotten, the outstanding success which attended our fight against the Government on the capitation fee in 1923. On that occasion, as secretary of a Division, I obtained the resignations of all but two of the local panel practitioners; and this was the general experience throughout the country. The result was the immediate collapse of the Government department and the granting of our reasonable demands. Exactly the same thing has just now taken place, again over the capitation fee. Success is ours if we will but have the courage to stand together (Montgomery's "discipline and comradeship").

But let there be no mistake on the issues of this plebiscite. A policy of appeasement is fatal. If once we begin to negotiate on the regulations we are doomed. Dr. Cox places the issues squarely before his readers. Everything is at stake. No matter how gilded the cage, a cage it will be if we barter our means of livelihood—the goodwill of our practices—however attractive the price which is offered to us (or will it be to our heirs, executors, and trustees?). As Englishmen whose forebears

fought for liberty let us strike a blow at all this regulating of our lives by the State, a blow which will resound throughout the Empire; and let us roundly refuse even to discuss regulations aimed at shackling us to the chariots of the politicians.—I am, etc.,

Barnes.

J. C. LYTH.

SIR,—My own part in the controversy over the National Health Service Bill has perforce been that of spectator, but having followed it carefully I have formed certain views from which the following emerge.

1. A democratically elected House of Commons with a full mandate, and having heard the views of all concerned, has decided that the Minister of Health has correctly assessed the public desire and in consequence has passed his Bill into law.

2. Many feel that this Act contravenes strongly held views among the medical profession. Now while it is our *right* as citizens to safeguard our own interests and our *duty* to express our opinions on the public welfare, we must be prepared to see our *advice* flouted, but we need not and must not allow our *interests* to be jeopardized without a struggle. Now that the Bill has been enacted we must make the best we can by negotiation to safeguard our own affairs, but we are no longer required to fight for the public aspects of the case because the public, through Parliament, has decided that our view of its welfare does not coincide with its own. Our duty to the public has been done to the best of our ability, and we can retire, I trust gracefully, from the stage.

3. As regards our own interests—do we advance these best by agreeing or by refusing to discuss with the Minister the details of the service which have yet to be defined before we can individually decide whether or no to enter it? The Minister, with his Bill passed, will be a very different person to deal with.

4. The advice showered upon us regarding the answer we shall give in the plebiscite has not, I feel, been devoid of much special pleading, a good deal of resentment at the Minister's methods in the pre-enactment stage, and a failure to set the issue against the proper background of economic facts and world trends in political and social affairs. To say "No" to entering a defined service is one thing, to say "No" to negotiating with a Minister of the Crown in the exercise of his statutory duty is something entirely different.

5. Dr. Dain talks of *insisting* "on our principles being established, by an amending Act or whatever it may be . . ." (italics mine). Now what House of Commons is going to bow to a demand of that sort? Especially one with a mandate as powerful as this House has. What, moreover, do the italicized words mean? Nothing; because an Act can only be amended by an Act, as of course Dr. Dain well knows. There is of course no semblance of an analogy with the N.H.I. controversy over the Spens Report.

6. In 1937 the Factories Act was passed. What should we have said, as trustees of much of the health of the country, if the employers or the unions had refused to discuss with the Secretary of State details of the countless statutory rules and orders which that Act entailed, simply because their personal views had been flouted or overridden by Parliament? What should we say to-day if employers or unions held up the work of the country because as a body they did not like the various Acts now affecting or about to affect coal, transport, and electricity?

I submit, Sir, that much bad advice is being given, and I fear it may result in effects far different to those envisaged and possibly very harmful to our profession and our prestige. I do beg our profession to lift its eyes from all that has been written of late about our "principles," from impressive voting figures at the Representative Meeting, and from its day-to-day preoccupations and anxieties, and to gaze for a moment at the far horizon. It stretches from Hiroshima to Lake Success, and the panorama is not such as to cause anyone to take a light-hearted view of the new world. Streams of lava are flowing from the political volcanos of the entire globe, and medicine has its great part to play in helping to direct the flow. Do we help best by accepting a democratically determined verdict we may not like or by putting ourselves out of step with the new life in our social and political structure?—I am, etc.,

Carbis Bay, Cornwall.

L. P. LOCKHART.

Mr. Bevan and Ourselves

SIR,—Mr. Bevan has intimated to all who may be interested that he thinks that most doctors are honest. How much of this may be merely damning with faint praise is left to our imaginations. One has, however, always the impression that Mr. Bevan has a poor opinion of the general practitioner, and that when he himself has a cold and his self-prescribed remedies have failed he calls in some "deep-browed Homer" of consultant rank—nothing less. The amazing thing surely is that most doctors are honest considering the scurvy treatment which so many of them have had at the hands of successive Ministers of Health for so many years.

And what of the honesty of politicians? What of the shifts, subterfuges, and evasions, particularly of those of ministerial rank when they are asked a straightforward question? When the Minister of Labour was asked in the House the other day by a Socialist member whether the Government was in favour of a 40-hour week, it took ten lines in the *Daily Telegraph* to express what should have been a simple yes or no; and having read it no intelligent person could tell whether this circumlocutory effort was synonymous with yea or nay. This is a cynical form of verbal cleverness, of course, and the rafters must fairly ring when politicians fight their battles o'er again in those places where they for-gather after "knocking off."

The doctor who practises "polypharmacy" (as is alleged) to win additional patients must really think of something more subtle, or the extent of his labours will probably not require even 40 hours a week for their execution.—I am, etc.,

Hove.

G. L. DAVIES.

The Basic Salary

SIR,—On the matter of part-payment by basic salary, there is one point on which the public and the profession might properly require very explicit information before the National Health Service comes into being. The question is: "What is the precise nature of the new obligations which doctors are intended to undertake by accepting a salary in addition to full capitation fees?"

As I understand the N.H.I. capitation fee, it is meant to recompense a doctor completely for all his normal services to each panel patient. By accepting a patient's panel card and signing it, and by later receiving a capitation fee from the State, a doctor undertakes certain well-defined obligations towards each patient, which he discharges by the full and proper performance of his medical and other duties, including the issue of prescribed certificates. Similar and even greater obligations appear to be contemplated in the new scheme. If payment were to be by capitation fee alone for each patient on whose behalf such obligations were to be undertaken matters would remain much as at present under the N.H.I. All medical attention and other services to one's patients would be covered, including the issue of a variety of certificates, some of which are really prescriptions for money from the Treasury rather than medicines from the chemist, and some expressions of opinion.

When, however, part-payment by salary in addition to full capitation fees is proposed, one must consider what further obligations could be covered by the salary and to whom these would be due, since the capitation fee already covers all one's services to one's patients. If the capitation fee under the new scheme does not in fact cover every such service as before, then the public and the profession should insist on knowing in detail which services are covered by capitation fee and which by salary. It may be intended that the basic salary should be in addition to a full capitation fee for each patient. Then one would want to know on whose behalf the State was paying this extra money, for the State, as employer, seldom pays money for nothing.

In default of an answer we may be guided by the Lord Chancellor (*Journal*, Nov. 9, p. 714), where he is reported as having said that the success of the scheme depended in large measure on getting satisfactory certification [to stop abuses]; giving something in the way of salary would have been a very valuable thing. In other words "satisfactory certification" is so crucial to the Treasury that they are prepared to pay double for it—once by a full capitation fee which, at least under the

N.H.I., covers the issue of all prescribed certificates, and second time by a basic salary which is presumably meant to ensure that such certificates will be "satisfactory."

It will remain for each doctor before joining such a scheme to decide for himself whether he wishes to undertake any such new obligations, especially while they remain undefined. For by accepting a salary, however basic, in addition to a full capitation fee, such a doctor would in fact become an under-paid minor official of the Treasury, who undertakes to issue "satisfactory" certificates (i.e., to express "satisfactory" opinions), to remain a contented, uncritical member of the bureaucracy, to accept government by regulation without appeal to the law, to accept direction, grading, and the sack, and even—who knows?—a uniform white coat to wear in the health centre. Mr. Bevan is right enough to emphasize that such a doctor would not be a civil servant. No civil servant would even consider accepting such conditions of work for the amount of a basic salary.

I propose that if the plebiscite should show a majority of the profession to be in favour of entering into negotiations with a Minister who doesn't negotiate, then two points should be insisted upon: first, that these new obligations be precisely defined; secondly, that it should be optional for any doctor joining the scheme to decline the basic salary, and with it these new obligations to the Treasury which have not been needed under the N.H.I. scheme—I am, etc.,

Shere.

G. I. WATSON.

The Negotiators

SIR,—While I am in favour of a negotiating committee entering into discussions with the Minister on the Regulations authorized by the National Health Service Act, I am extremely doubtful whether the present members of that committee are the right persons to negotiate.

I would suggest that, should the results of the present referendum show that a majority of the Association are in favour of continued negotiation, new members of the Council and of the Negotiating Committee should be elected. For the documents forwarded with the voting form make it clear that our present representatives hold views which are so inflexible as to make any form of negotiation impossible.

Should the majority of the Association vote against negotiation, it would seem reasonable to allow those members who are interested in maintaining a more co-operative attitude (despite any differences of opinion there may be between the Minister and themselves) to elect their own representatives. Those members of the B.M.A. who may wish to serve in the new National Health Service will naturally wish to negotiate but it is senseless for them to be represented by a majority who have no intention of working in the new Service—I am, etc.,

London, N.W.3.

B. DELISLE BURNS.

Pay of Pathologists and Bacteriologists

SIR,—For some years I have been puzzled by what seems to me one of the mysteries of our profession. I refer to the salaries paid to the junior pathologists and bacteriologists working in laboratories throughout the country.

In the first place, the word "junior" is a misnomer, since most of these men and women are doctors of experience in their specialty, and many hold higher degrees in their subject. Their salaries, however, have been at the lowest level for a very long time, and the young doctor who wishes to specialize in laboratory work finds himself forced to live somewhat precariously for many years. He is expected to do highly specialized work and to give advice to his far-better-paid brothers in practice; his daily routine is of necessity meticulous and painstaking, demanding a concentration and attention to detail second to none; the amount of study he has to do is enormous compared to, say, the general practitioner: for this he may be offered a salary of from £350 to £500 per annum.

It is only the few who eventually take charge of a laboratory who receive a financial return even remotely comparable to the earnings of the other branches of medicine. Yet the pathologist-bacteriologist is reckoned by most as a specialist; why then is he not paid as one? His work is recognized as essential in every community. Now, Sir, when a man's work becomes important he usually expects to be paid accordingly; it there-

seems odd that laboratory work constitutes the poorest branch of medicine.

I am a "laboratory doctor" because I find the work as interesting as the clinician finds his patient, but I object strenuously to a system which demands of me the highest efficiency in specialized work on the one hand, and on the other gives the practising clinician a comparatively comfortable life while forcing me literally to watch every penny. Such luxuries as a home of his own or a car are as a rule unknown to the laboratory doctor, while the activities of his wife and family are restricted in a way not usually associated with a specialist in our profession.

I should like to ask a question: Could the clinician and laboratory doctor change places? Well, in emergencies I have seen many laboratory doctors carry on medical practices and conduct them to the satisfaction of all concerned. I regret I have not witnessed the spectacle of a clinician or general practitioner faced with the histological diagnosis of a tumour, or the performance of a routine Wassermann test. In other words, is the laboratory doctor a specialist in the real sense of the word? If the answer is "Yes" then we have the strange position of a specialist receiving a salary about one quarter that earned by the non-specialist.

I regret, Sir, that for obvious reasons I must sign myself
LABORATORY DOCTOR.

Tetra-ethyl Lead Poisoning

SIR,—The article (Nov. 9, p. 681) entitled "Tetra-ethyl Lead Poisoning" by Dr. D. A. K. Cassells and Prof. E. C. Dodds leaves no doubt that organic lead had been inspired by all the cases. But in view of the known hazard I should like to know whether they underwent a preliminary physical examination; and more details about their personal protection would have been interesting—e.g., were they instructed to wash their hands after eating during the working shift, and were they forbidden to chew tobacco while engaged at their task?

While alcoholic poisoning is included in the differential diagnosis, the authors do not state whether the gas-free condition of the atmosphere in the petrol tanks was confirmed by tests. The wide range of urinary lead analysis—0.10 to 0.48 mg. per litre—can leave no doubt in the mind that the cases had been exposed to a particularly heavy lead exposure. But the leptomeningitis found at necropsy in Case 1, together with the very early onset of subjective symptoms in Case 4, are suggestive at least of industrial solvent poisoning. The absence of a basophilic response is to be expected, as the absorption of massive doses of the toxin over a short period of time would not allow an adequate haemopoietic stimulation.—I am, etc.,

D. G. ROBINSON.

Barnsley.

Abacterial Pyuria

SIR,—I have followed with interest the recent correspondence in the *Journal* on abacterial pyuria. In particular, I was interested in the theories as to its causation. In one of the early articles a spirochaete was suggested as a possible causal agent. This was supported by the fact that neosarsphenamine, which has a dramatic curative effect in this disease, is also effective against many spirochaetes. One wonders whether penicillin, which is very effective in spirochaetal diseases, would have any influence on this condition. Should it do so, it would be further evidence in favour of this theory, as penicillin does not affect viruses or *Trichomonas vaginalis*, which have been suggested as alternative causes. So far as I know, there has been no mention of penicillin treatment in any of the published articles. I have not, as yet, had the good fortune to encounter this condition in general practice and so have had no chance to test this idea.—I am, etc.,

Croxley Green.

D. P. WHEATLEY.

Abacterial Pyuria presenting as Urethritis

SIR,—With reference to Dr. R. T. Burkitt's letter (Oct. 26, p. 625) concerning my article on abacterial pyuria (Oct. 5, p. 493), I beg to submit the following reply. (1) The possibility of acid-fast infection was considered in all cases. The cases were discussed from this angle with a genito-urinary surgeon and a specialist physician who were both interested

in this condition and had treated successfully with neosarsphenamine similar cases. Does pyuria, caused by an acid-fast infection, clear up dramatically and remain clear after N.A.B. injections? I would refer Dr. Burkitt to Mr. H. Donovan's article in the *British Medical Journal*, 1945, 2, 12. (2) In the course of my tour of West Africa during the war I have found gonococcal cystitis *per se* a very rare condition indeed. The only cases of cystitis I have seen have been a basal type associated with acute prostatitis; but in the cases described in the article there was no evidence, on rectal examination, of prostatic involvement.

Perhaps I did not make it clear in the article, but the cases presented had no urethoscopic evidence of anterior urethritis. Cystitis of *Bact. coli* origin, for example, may present as a false urethritis—illustrated by the fact that a special treatment orderly of mine came to see me one morning, looking very puzzled, complaining of a urethral discharge associated with pyuria and frequency. He certainly had a purulent urethral discharge (pus cells + + +), but his correct diagnosis, confirmed by culture and cystoscopy, was *Bact. coli* cystitis.

Since arriving in Italy I have seen a further case very suggestive of abacterial pyuria, of which the following is the history:

The patient, a private soldier aged 28, with eight years' service, was admitted on Feb. 8, 1946, with what appeared to be a simple uncomplicated gonococcal urethritis. The urethral smear was positive for G.C. A routine course of 150,000 units of penicillin (5 × 30,000, two-hourly) was given. As the urine remained hazy a course of 30 g. of sulphathiazole was given over a period of six days. The anterior urethritis was cured, but the pyuria persisted. On Feb. 18 a further 150,000 units of penicillin was given, and, following a normal white cell count, a further course of sulphathiazole. On Feb. 25, as there was still no improvement in the condition of the urine (a mid-stream specimen on Feb. 20 revealed albumin +, pus cells + + +, R.B.C. + + +, epithelial cells +, casts nil, culture sterile), a pyrexial reaction was induced by intravenous T.A.B., but even this had no effect.

The case was first seen by me at this stage on March 1. On account of the persistent pyuria in spite of the above treatment, the marked frequency, the absence of prostatic involvement and of a true urethritis, and a negative Kahn, I treated the case with four injections of 0.3 g. N.A.B. on March 1, 3, 5, and 12. There was an immediate cessation of the almost intolerable frequency and a rapid clearing of the urine. On March 12 the urine was perfectly clear and the patient had no complaints. On a final examination at the end of March, prior to his release, he was in the best of health.—I am, etc.,

A. B. FIELDSEND,
Capt., R.A.M.C.

Breast Cancer Treated with Stilboestrol

SIR,—In May, 1946, I was asked to see a Mrs. X., aged 91 years, and found that she had a swelling in her left breast about the size of a large egg. It was hard, irregular, and caused puckering of the skin in front, but did not appear to be adherent behind. There was no doubt that it was a carcinoma. She refused to leave home to have any hospital treatment at her age, and so I started her on 3 mg. stilboestrol daily. Within a few weeks the breast commenced to soften and the swelling gradually diminished in size. When seen on Oct. 15 no swelling was visible on inspection, and only a small thickened area of breast tissue could be felt on palpation—about the size of a cob nut.

Apart from some deafness she is extremely well and active for her age.—I am, etc.,

Meopham.

W. D. HASLER.

Double Gastric Ulcer

SIR,—To Mr. M. Kaye's article on "Double Gastric Ulcer with Perforation and Haemorrhage" (Nov. 9, p. 695) we would add our observations on 5 established cases of double chronic peptic ulceration.

ABRIDGED CASE REPORTS

(1) A newspaperman aged 63 was sent in as a case of subacute intestinal obstruction. His presenting symptom was vomiting. Examination revealed epigastric rigidity. Past history strongly suggested chronic gastric ulcer. He was put on graduated ulcer-

diet. A large haematemesis of 2 pints (1.1 litre) occurred 7 days later. A blood transfusion was given on usual indications and improvement followed only to be punctuated by another haematemesis. Investigations included test meal, which indicated high total acid. Radiography demonstrated an ulcer on lesser curve and a duodenal ulcer. Progress uneventful.

(2) A housewife aged 58 admitted on history of 7 days' weakness, melaena, and recent haematemesis. Past history pointed to symptoms of gastric ulcer dating from 1933. She had small repeated haematemeses, and response to transfusion was good. Radiography revealed two gastric ulcers. She was discharged in due course.

(3) A woman aged 70 was admitted as an "acute abdomen." Past history yielded vague dyspeptic symptoms culminating in an attack of upper abdominal pain associated with vomiting of two days' duration. Abdominal section showed blood-stained fluid and early peritonitis. On inspection of stomach a large prepyloric perforation below lesser curve was noted. Induration was a feature. On opening lesser sac a gastric mass posteriorly was attached to pancreas without obvious signs of malignancy. On separation, a larger ulcer presented. Ulcers were closed. Histological examination demonstrated chronic ulceration and ruled out neoplastic change. Condition on discharge was satisfactory.

(4) A middle-aged Chinese man was admitted with a diagnosis of pulmonary tuberculosis and died from this malady. At necropsy two chronic ulcers were found on lesser curve about 1 in. (2.5 cm.) apart.

(5) A man aged 69 was admitted with vague abdominal pain occurring mainly after meals, of several years' duration. Radiography one year previously had yielded negative results. Three days later he vomited three-quarters of a pint (430 ml.) of "coffee grounds" fluid. In spite of blood transfusion and other supporting measures he deteriorated rapidly and died. Necropsy findings—(a) Oesophagus: dilatation of lower end, with ulcer 3 cm. by 2 cm. immediately above ridge separating oesophagus from stomach. Base indurated and adherent to left lung. Floor of ulcer presented several small oozing points. (b) Stomach: ulcer 2.5 cm. by 2 cm. immediately distal to gastro-oesophageal ridge. Floor smooth and fibrotic.

This group of five cases is drawn from an ulcer case list numbering 100 per year approximately. The lesions were demonstrated radiographically (two), post mortem (two), and one at operation.—We are, etc.,

Amoebiasis

SIR,—Correspondence on amoebiasis must come to you with a considerable time-lag, as those who contribute are usually remotely situated. Dr. M. L. Mason's letter (Aug. 31, p. 308) is eminently practical, and stresses aspects which are too often left unstressed and which are so important that I hope colleagues at home, unused to many peculiarities which the condition is apt to exhibit, will take his letter as a timely warning. The infective stage of the amoeba being the cyst adapted to withstand adverse conditions such as drought, gastric juice, etc., cyst-passers reaching the U.K. are liable to start the disease in its most active form over wide areas. Where rural sanitation still exists, this may be more than a possibility; where water sanitation obtains, there is no use expecting cysts to perish due to the anaerobic action of septic tanks and sewage systems; and there is always the house-fly. There is also the carrier who can infect food; I have often examined matter removed from under finger-nails and found cysts present. In view of the fact that the efficacy of treatment of amoebiasis still leaves much to be desired, even treated cases will have to be considered as potential carriers.

To comment on Dr. Mason's typing of symptomatology, I would say that diarrhoea is far from common, and may often be so slight that it is not remembered when, long afterwards, the patient shows symptoms suggesting chronic appendicitis or peptic ulcer. This type is very common, but I do feel that type 4, i.e., the malaise and irritability type, is by far the most frequent. Unfortunately, even if numerous specimens are examined, the stools are usually negative. This is probably because the amoeba is a commensal for quite lengthy periods, and has no need to encyst and find a new host. These negative results may mislead the inexperienced; also the repetition of tests takes up much time, whereas early diagnosis would enable the practitioner to notify his M.O.H. at least a week earlier, even supposing he were lucky enough to find one stool positive

by ordinary straight examination. A practice of mine for the last eighteen years has been to give such cases one injection of 1/2 to 1 gr. (32 to 65 mg.) emetine, and examine the stools next morning. I have rarely failed to find cysts when this has been done. They are usually with only one or two nuclei, in other words, finding a new host in a hurry. The reason, of course, is elementary zoology—when conditions become unfavourable (for instance, due to emetine) cysts are formed and pass out to seek a more accommodating host. This provocative test is particularly useful in the chronic patient, whose stools will otherwise always be negative.—I am, etc.,

Arua, Uganda.

A. FORBES BROWN.

"Analgesic" or "Anaesthetic"?

SIR,—Dr. J. N. Fell (Nov. 9, p. 711) objects to the use of the "ugly term analgesic," and while it is obvious that a distinction exists it is only one of degree. The term "analgesic" implies the loss of pain sensations only and "anaesthetic" the loss of all sensations. But I have found that there is an important difference. If chloroform is dropped continually on a mask over the mouth and nose of the patient, sensation of pain is very quickly lost, long before loss of consciousness, and it is well known that hearing may remain quite acute for a considerable time and the anaesthetist has to be careful not to discuss the patient's symptoms until anaesthesia is complete. While analgesia is rapidly produced, the auditory sense is the last to go. The object of the surgeon should be not only curative, but also the complete abolition of any pain. For instance, the removal of a gauze packing in an abdominal wound will cause very acute though temporary pain, which could be completely avoided by producing analgesia by dropping chloroform on a mask continually for one minute only. It was my custom to tell the patient that he or she would be quite aware of the withdrawal of the gauze packing but it would be quite painless, and it became my custom to go round the ward with a mask and a bottle of chloroform. The patient had absolutely no pain and no other symptoms of any kind. In one case a friend of mine whom I visited in the hospital had double pneumonia and was very seriously ill. He told me he had a raging toothache but was refused any anaesthetic owing to his condition. I gave him chloroform for one minute and then extracted the tooth quite painlessly.—I am, etc.,

Worthing.

HERBERT H. BROWN.

Definition of Health

SIR,—I should like to endorse Dr. W. F. Felton's pertinent remarks (Oct. 19, p. 591) concerning the definition of health adopted by the World Health Organization. I have long believed that much confusion of thought and inadequacy of practice, especially in the realm of "social medicine," can be traced to the vagueness of our conception of health. I have pointed out elsewhere (*Medical Officer*, 1946, Mar. 30, p. 118) that in common speech we use "health" indiscriminately, both to refer to a specific ascertainable condition (e.g., he recovered his health) and also as though it were practically synonymous with "condition" itself. If the first is used it is by no means illogical to oppose health and disease, and to define each as the absence of the other. I therefore suggested that we should accustom ourselves to the wider use. This demands a qualifying adjective before it can be applied to particular cases (as good health, better health, indifferent health), and so the true antithesis of "good health" and "bad health" emerges. Disease is relegated to its proper place, which is that of one factor, a very variable one, in particular cases of poor health. Thus a mere grammatical exploration of the term does seem to me notably to clarify our thinking. May I add my own definition of health, which is, in its simplest form, "the total condition of the personality." This provides for the dynamic quality which Dr. Felton so rightly wishes to emphasize. Our aim would be that each individual might continually approach his "best possible" total condition. In this way, goal can move constantly ahead of achievement, and a real constructive "positive" outlook is assured.—I am, etc.,

Gravesend.

HERBERT S. DAVIES.

Obituary

J. L. BROWNLIE, M.D., D.P.H., F.R.S.Ed.

James L. Brownlie, who died on Nov. 12 in Edinburgh, succeeded the late Dr. John Parlange Kinloch as chief medical officer of the Department of Health for Scotland in 1932 but resigned that post at the end of 1936 after being on sick leave some time.

James Law Brownlie was a student of Glasgow University and graduated M.B., Ch.B., and five years later received high commendation for his M.D. thesis on the problem of the diphtheria carrier. He also took the Cambridge D.P.H., and during his tenure of office in Edinburgh received the diploma of R.C.P.Ed., and was elected F.R.S.Ed. He had been for four years resident medical officer at the Glasgow Corporation fever hospitals and for six years assistant bacteriologist in the Glasgow Corporation laboratory. During this part of his career he contributed papers to medical journals and became known as an investigator of food-borne infections. His next post was that of bacteriologist and pathologist for the County of Lanark. In 1930 he moved to Edinburgh to take up duty as a medical officer of the Department of Health for Scotland, and one of his main tasks was concerned with the co-ordination of the hospital services of Scotland; he also represented his Department on various scientific bodies and committees. Brownlie is honorary secretary of the Section of Micro-Biology (including Bacteriology) at the Annual Meeting of the B.M.A. held in Glasgow in 1922, and vice-president of the Section of Public Health when the Association met in Dublin in 1933.

Dr. JOHN WILLIAM LINDSAY, who died at his home in Ealing on Nov. 9, was a practitioner of the "covered-wagon" days in the cattle country of South America. He was born in Aberdeen, where he graduated M.A., M.B., Ch.B., gaining the medals in surgery and in obstetrics, and then joined the South American Missionary Society beginning pioneer medical work in the Paraguayan Gran Chaco in 1900. In 1902 he set up in private practice at Belén in eastern Paraguay, where, except for service to the R.A.M.C. on the western front during the 1914-18 war, he worked until his retirement to England in 1934. He quickly acquired a very great professional reputation, and it was not uncommon for patients to travel six weeks by bullock-cart to see him. In addition to frequent revolutions his locality provided all the excitements of "wild-west" frontier life and, though he was beloved by all, he narrowly escaped many a bullet. A deeply religious man with a strong evangelical leaning he built a local mission-hall, and among other attainments Mr. Lindsay had a knowledge of a dozen dialects and was particularly attracted to Guarani, the language of an extinct race, in which, though it had not been reduced to writing, he published a translation of the New Testament which he had made from the original Greek. During the Gran Chaco war of 1932-4, he equipped and managed a military hospital for Paraguayan troops, did much to arouse interest in the work of the British Empire Leprosy Relief Association, and in the recent war worked with the Ministry of Economic Warfare as Spanish expert until his health broke down. He is survived by his wife and three children (one of them in the I.M.S.) who shared his South American adventures.

Dr. ALEXANDER MACINTYRE, of Airdrie, Lanarkshire, who died some weeks ago at the age of 67, was a native of the parish of Gairloch, Wester Ross. He studied medicine at the University of Glasgow, graduating M.B., Ch.B. in 1902, and started work at Airdrie on the first day of 1903 as assistant to the late Dr. Gemmell, whom he succeeded. Apart from two and a half years of service as a medical officer with the Forces in the war of 1914-18 Dr. Macintyre spent all his medical career in that neighbourhood, where his skill and devotion won the regard of all his patients. He was particularly well versed in Gaelic tradition and lore, and a fluent speaker of the language; he helped to edit several Gaelic books. He was a member of the Glasgow and Inverness Gaelic Society, and an address he gave in January, 1945, was so excellent in manner that the Society had it printed and published in booklet form under the title *Home Culture*. He will be greatly missed not only by his own community but by a wide circle of friends and admirers of his scholarly mind. He had been a member of the B.M.A. since 1917.

Universities and Colleges

THE PLEBISCITE

Statement by Sir Alfred Webb-Johnson

The following statement was made by the President of the Royal College of Surgeons of England, Sir Alfred Webb-Johnson, at a meeting of plastic surgeons held at the College on Nov. 20.

"Every medical practitioner is being asked to give an answer to the following question: Do you wish the Negotiating Committee to enter into discussions with the Minister of Health on the regulations which he is authorized to make by the National Health Services Act? I hope that all practitioners will give this question most serious consideration. I trust that they will not lightly make it difficult for the responsible leaders of the profession to enter into negotiations in which the Minister is now at liberty to take part. It must be borne in mind that a vote in favour of discussions with the Minister does not register approval of the Act in every detail. A vote in favour of discussions does not commit any practitioner to accepting service under the Act. There are parts of the Act which, in the judgment of the majority of the profession, will not give the public the best service. But the Act probably pleases no one entirely. There are obvious dangers to be guarded against. Discussions will, however, provide opportunities for negotiation on many points which still need clarification, in spite of the debates in Parliament. They will also provide opportunities for helping to plan most of the machinery of the Service, and to mould much of the policy which remains to be settled by regulations."

UNIVERSITY OF LONDON

John McMichael, M.D., has been appointed to the University Chair of Medicine tenable at the British Postgraduate Medical School, from Oct. 1.

Stuart Dunsmore Elliott, M.D., has been appointed to the University Readership in Bacteriology tenable at the London Hospital Medical College, from Oct. 1.

The following candidates have been approved at the examination indicated:

THIRD M.B., B.S.—15P. J. Blaxland, 15P. Patricia Chippindale, 15A. T. Cook, 15B. A. Davis (University Medal), 15F. V. Flynn, 15Kathleen A. M. Friih, 15P. W. S. Gordon, 15A. J. Harrold, J. M. Alderton, Elizabeth J. Allday, R. H. Anthony, J. J. Ashken, M. Atkinson, D. A. Bailey, D. W. Bain, D. N. Balsekar, A. D. Bingham, P. J. Banks, G. F. Barnes, P. J. H. Barron, A. C. Barthels, D. Bartlett, H. N. Baylis, R. W. Bell, A. Benjamin, A. J. Berrill, M. A. Birnstingl, R. W. A. Bottoms, Daphne V. Bousfield, L. W. Bowen, A. C. Boyle, H. G. Broder, M. H. Brook, L. Broumache, E. K. Brownrigg, Brenda M. Buck, D. E. Burgess, G. L. Burgess, J. Candy, J. R. Carter, Rosemary Cartledge, C. L. Casimir, F. E. de W. Cayley, F. C. Chesterman, C. J. Christmas, Betty L. Coles, R. B. Coles, H. P. F. Corbin, Anne N. M. Crane, D. W. J. Cullingford, M. J. Cutler, D. G. L. Davies, P. R. Davis, A. J. A. Dawes, P. E. A. de Caestecker, J. F. de la Frenay, K. R. Dempster, H. S. de Silva, C. F. Donovan, D. M. D. Evans, M. E. Fearnley, B. R. Finlay, F. J. Fish, M. L. H. Flindt, A. F. Forbat, R. H. Fox, C. J. G. de L. Franklin, F. E. Fraser, J. G. Gant, Mary P. Gibson, C. E. J. Glaisher, H. H. Glatston, S. G. Gordon, Rosemary D. Graham, Helen C. Grant, G. R. Green, C. J. Griffin, G. L. Gryspeerd, A. W. Hagger, G. J. L. Hamilton, N. Hamlin, J. Hankinson, R. P. Harwood, P. J. D. Heaf, I. T. T. Higgins, A. B. Hill, R. D. Hoare, R. K. Hollows, R. J. Howat, A. Hughes, R. W. Hughes, J. R. Ivey, I. Jaffa, G. V. Jaffé, J. James, J. G. Jamieson, C. W. L. Jones, D. W. W. Jones, K. C. D. Jones, T. G. Jones, P. Jordan, A. R. Kagan, I. A. Kellock, R. E. Kelly, Marjorie A. C. Kuck, M. Kugler, O. G. Lane, J. L. Lawrence, Wendy E. Lewington, Elaine Lister, G. H. Luffingham, J. Lustigman, K. A. McCluskey, I. J. MacDonald, H. W. Macintyre, I. Mackenzie, Freda S. Maclover, R. G. C. MacLareo, R. Macpherson, J. D. Manning, E. A. W. Marien, S. Mattingly, W. R. May, E. V. M. Medill, J. N. Mickerson, R. Moolan-Feroze, I. A. H. Munro, C. P. Newcombe, K. H. Nickol, C. Pearce, R. A. O'G. Pearson, J. H. Pendered, Thelma M. Phelps, B. H. Pickard, Eva Pickford, C. M. C. Potter, Prudence M. Proudlove, J. I. Pugh, J. H. Raphael, Jean M. Raybould, D. D. Rees, M. F. Rémy, D. I. Roberts, J. E. Russell, M. McC. Russell, A. J. Ruzicka, R. C. O. Saunders, Enid Scholfield, Valerie Scotland, A. G. Seaman, R. P. Shields, Patricia D. Shurly, N. R. W. Simpson, I. P. D. W. Skempton, P. A. J. Smith, R. J. H. Smith, J. L. Souster, M. J. Squires, R. J. Stanley, Dorothy M. Stanton, J. E. T. Strickland, M. Strobe, Gwendolyn M. Sutton, G. F. Swann, C. K. M. Thacker, D. M. E. Thomas, I. J. Thomas, H. N. Waller, J. H. Wallis, R. G. Watson, B. G. Wells, J. Whitwell, W. B. Whowell, A. P. H. Wilkinson, J. R. B. Williams, Lorna E. Williams, T. B. Williamson, J. T. Woodall, Joan D. Wrigley, Angela R. Young, C. J. Zerny.

¹With honours. ²Distinction in pathology. ³Distinction in hygiene and forensic medicine. ⁴Distinction in medicine. ⁵Distinction in surgery. ⁶Distinction in obstetrics and gynaecology.

UNIVERSITY OF LEEDS

Digby Chamberlain, Ch.M., F.R.C.S., has been appointed Professor of Surgery in the University, from Oct. 1.

The title of Emeritus Professor has been conferred on William MacAdam, M.D., F.R.C.P. (professor of medicine), Peter Lindsay Sutherland, D.Sc., M.B. (professor of forensic medicine), and Charles Wilfred Vining, M.D., F.R.C.P. (professor of children's diseases).

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Meeting of Fellows and Members

At the annual meeting of Fellows and Members on Nov. 13 the President, Sir Alfred Webb-Johnson, Bt., presented the report of the Council. It was desired to create, under a new Charter, Faculties within the College, to elect to the Fellowship, each year, not more than four Members who had been practising dental surgery over a long period, and to grant a Fellowship in Dental Surgery. They were to be congratulated on securing the services of Prof. F. Wood Jones and two new curators for the anatomy department. The John Hunter medal and prize had been awarded to Dr. Joan Margaret Ross for her outstanding work in pathological anatomy. Two prizes of £1,000 each, the gift of Mr. Charles L. Mayer, of New York, had been awarded to Mr. Terence Millin in recognition of his contribution to the advancement of the surgical treatment of the prostate, and to Prof. E. C. Dodds for his researches in the field of the synthetic hormones.

The College and the National Health Service Act

The President added some remarks on the National Health Service Act. There was, he said, much good in the Act, and important concessions had been made by the Minister as a result of their representations. Nevertheless, a good deal of anxiety still prevailed. In fighting for the freedom of the profession they were not fighting for any vested interests, but for an essential freedom of the people. The Lord Chancellor had given the President assurance that specialists who did not join the service would have freedom in an honorary capacity to treat their private patients in hospital, and had accepted an amendment with that in view. He hoped that the Negotiating Committee would continue to enjoy the confidence of the profession.

Mr. C. E. Beare moved:

That this meeting of Fellows and Members of the Royal College of Surgeons urges the Council to do its utmost to prevent the penalization of private practice by the restriction of the medical staffs of hospitals to those who take part in the State Medical Service.

He expressed the gratitude of the Fellows and Members to the President and other members of Council who had served on the Negotiating Committee, but considered it not quite clear from the Lord Chancellor's assurance whether the reference was to specialists on the staffs of hospitals in an honorary capacity or to those who were in the Service. The President pointed out that the amendment accepted by the Government inserted the words "whether in an honorary or paid capacity," but Mr. Beare was still doubtful about the interpretation of this amendment. It was possible that those at present on the staffs of hospitals would not be re-elected unless they undertook State service, and he feared they might be debarred from attending private patients in these hospitals. Mr. Dickson Wright seconded the motion.

Dr. H. Guy Dain considered that the accepted amendment made very little difference, for the Minister had stated categorically that he would not allow any private practitioner who was not in the Service to practise in the State hospitals, and this referred not only to the public but to the private wards. If and when the State owned all the hospitals it would be the end of private specialist practice. It would be necessary to establish nursing homes outside the Service, and even then there was no guarantee that they would not be taken over. The President said that the Lord Chancellor's assurance, which had been confirmed by the Minister, must go some way to relieving anxiety, but he fully appreciated Mr. Beare's point, especially as it related not to those already in practice but to those coming into practice in the future and who did not comply. The Negotiating Committee should clear up the point.

On Mr. Beare's motion being put to the vote, twenty-six stood in favour of it, but this number was short of the quorum required under the rules of the College, and a special meeting of Fellows was called for Nov. 29.

At an ordinary meeting of the Council of the College, held on Nov. 14, with Sir Alfred Webb-Johnson, Bt., President, in the chair, the Honorary Gold Medal of the College was awarded to Sir Alexander Fleming, F.R.S., F.R.C.S., in appreciation of his distinguished work and particularly in recognition of his discovery of penicillin.

Prof. Ian Aird, F.R.C.S.Ed., professor of surgery at the British Postgraduate Medical School, was elected *ad eundem* to the Fellowship of the Royal College of Surgeons of England.

It was reported that the trustees of the Sir Halley Stewart Trust had made a grant to the College for a research fellowship, and Mr. H. Fletcher Lunn, anatomical curator, was appointed as the first Sir Halley Stewart Fellow. Mr. Alan C. Perry (London), Sir Hemeage Ogilvie (Guy's), and Mr. R. M. Handfield-Jones (St. Mary's) were elected members of the Court of Examiners. Mr. R. J. Last, M.B., anatomical curator, was elected as the first Bland-Sutton Research Scholar. It was reported that the special trustees had elected Mr. F. H. Masina, F.R.C.S., as a Profit Research Student

for the investigation of the pathology and treatment of carcinoma of the bladder. The Hallett Prize was awarded to Mr. Robert Po Melville, of the University of Sydney. Hugh Kelson Ford (Epsom College and the London Hospital) was nominated as the fifty-fourth Jenks Scholar.

Diplomas of membership were granted to the 114 successful candidates whose names appeared in the report of the meeting of the Royal College of Physicians of London as recipients of the Licentiate of that College (Nov. 23, p. 799).

Diplomas in Child Health, in Medical Radiotherapy, and Medical Radio-Diagnosis were granted, jointly with the Royal College of Physicians of London, to the successful candidates whose names were included in the report of the meeting of that College.

The following lectures will be delivered at the College (Lincoln Inn Fields, W.C.) at 5 p.m.: Dec. 5, Imperial Cancer Research Fund Lecture, by Dr. B. D. Pullinger, "Cystic Disease of the Breast Human and Experimental." Dec. 12, Robert Jones Memorial Lecture, by Mr. W. Rowley Bristow, "Injuries of the Peripheral Nerves in two World Wars." Dec. 17, Erasmus Wilson Demonstrations, by Mr. R. W. Raven, "Melanoma and Related Tumours." Dec. 19, Thomas Vicary Lecture, by Dr. E. Ashworth Underwood "Naval Medicine in the Ages of Elizabeth and John."

Medical Notes in Parliament

Welfare of the Deaf

Mr. KEY replied on Nov. 20 to a discussion on the welfare of the deaf. He said the Government recognized that, important as were hearing aids, the treatment of infectious diseases in childhood and prompt attention to the prevention of deafness were more important. The Ministry of Health was preparing comprehensive measures for prevention, diagnosis, and treatment of deafness as part of the National Health Service, and was armed with authoritative recommendations from those committees which the Medical Research Council had set up in 1944 at the request of the Departments concerned in this problem. There was not likely to be difficulty in persuading the Medical Research Council to undertake further research. By Section 16 of the National Health Service Act, the Minister himself had power to conduct or to assist by grants research into any matters relating to the causation, prevention, diagnosis, or treatment of illness. Deafness would be included in the provision, and the Department would use these new powers fully to see that such investigation was made. He did not suggest it would be possible to build up the complex organization for the care of the deaf and to have it operating everywhere by the date when the National Health Service Act would come into operation. But deafness clinics, under trained specialists, would be developed as part of the hospital and specialist services as quickly as available resources allowed. Up-to-date and effective means of testing deafness and of fitting the patient with the kind of aid which would benefit him would not be overlooked. An advisory committee on the welfare of the deaf would be set up when the time seemed ripe for it.

Mr. BEVAN stated on Nov. 21 that free issue of deaf aids could not begin before the National Health Service came into operation.

Streptomycin.—Mr. HERBERT MORRISON, on Nov. 18, said that the Medical Research Council had arranged for controlled clinical trials of streptomycin, as soon as supplies were available, to determine its value in tuberculosis and other conditions and the best methods for its use. Funds were being allocated for the cost of this work, including purchase of the necessary quantities of the product.

Dermatitis in Coal-miners.—Mr. DAVID GRIFFITHS asked on Nov. 19 for the numbers of cases certified by the certifying surgeons of coal-miners suffering from dermatitis from January, 1938, yearly up to and including December, 1945. Mr. JAMES GRIFFITHS explained that separate figures for coal-miners were not available, but the number of cases among miners generally, the majority of whom had been coal-miners, were as follows:

1938	..	254	1942	..	884
1939	..	305	1943	..	1,207
1940	..	402	1944	..	1,506
1941	..	573	1945	..	1,867

Staffing of Mental Hospitals.—Mr. BEVAN stated on Nov. 21 that during the past twelve months the accommodation in England and Wales for mental defectives had increased by 177 beds. On Jan. 1, 1946, mental hospitals were overcrowded to the extent of 13,176 patients, or 11.5% of the total accommodation. The number of nursing staff employed in mental hospitals and mental deficiency institutions had increased by 620 during the twelve months ended June 30, 1946, bringing the total to 25,840, just over half of whom were fully trained.

To Maintain proper Nutrition During and After Pregnancy

THE results of modern ante-natal care have emphasized the importance of proper nutrition of the expectant mother, in securing a normal pregnancy, labour and puerperium, and in endowing the infant with an initially sound constitution.

The use of 'Ovaltine' throughout pregnancy goes far towards ensuring this ideal state of nutrition. 'Ovaltine' is a natural food tonic prepared from milk, eggs and malt extract with a cocoa flavouring. 'Ovaltine' is delightful to the taste and is so readily digestible that unsettled digestion does not preclude its use.

During lactation its use enriches the milk and permits the mother to continue adequate feeding until the normal time for weaning occurs.

Sulphathiazole

Sulphathiazole is one of the most active of the Sulphonamide drugs for the treatment of pneumococcal, meningococcal, gonococcal and haemolytic streptococcal infections. Many regard it as the sulphonamide of choice for the treatment of urinary tract infections.

May & Baker's sulphathiazole preparations are protected by British Patent No. 533,495, which was granted on 24th May, 1946, jointly to May & Baker Ltd and Ciba Ltd, of Basle.

SHORT-WAVE THERAPY

IN GENERAL PRACTICE

Of many painful afflictions, fibrositis, sciatica, rheumatism, neuritis, sinusitis and chronic inflammation are, perhaps, the most common. Every General Practitioner is called upon to treat the sufferers and in many cases will prescribe Short-Wave Therapy. If this treatment is applied by means of the Marconi Theracoupler, the patient will derive maximum benefit since, by this instrument, deep tissue heating is most effectively administered.

Many doctors are already using the Theracoupler which is extremely simple to operate. Further particulars will gladly be supplied on request.

The B.D.H. range of Penicillin preparations includes:

PENICILLIN

Vials containing 100,000 int. units, 200,000 int. units, 500,000 int. units and 1,000,000 int. units

PENICILLIN EYE OINTMENT B.D.H.

(Penicillin Ointment for the Eye B.P.)
Collapsible tube of 1 drin.

PENICILLIN LOZENGES B.D.H.

(Lozenges of Penicillin B.P.)
Container of 50

PENICILLIN (Oil-wax) SUSPENSION B.D.H.

(Oily Injection of Penicillin B.P.)
Vials containing 10 ml. and 20 ml.

PENICILLIN OINTMENT B.D.H.

(Ointment of Penicillin B.P.)
Container of 1 oz.

Details of dosage and other relevant information on request

No. 45

EPIDEMIOLOGICAL NOTES

INFECTIOUS DISEASES AND VITAL STATISTICS

For the print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Nov. 9.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) the 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or return available.

Disease	1946					1945 (Corresponding Week)

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

It is still not possible to publish the return of births and deaths for Eire for the weeks ending Oct. 26, Nov. 2, and Nov. 9.

Discussion of Table

In England and Wales infectious diseases were more prevalent during the week, and increases were recorded for cases of measles 613, scarlet fever 136, acute pneumonia 116, whooping-cough 41, and diphtheria 40. The only exception to the general trend was a fall in the incidence of paratyphoid 36.

The largest increases in the notifications of measles were Kent 160, Lancashire 102, and Northumberland 89; the largest decreases were Durham 74 and Middlesex 43. Cases of scarlet fever increased in number in most areas of the country, and notably in Middlesex 36 and Yorkshire West Riding 27. The only large variation in the trend of whooping-cough was a decrease in incidence in Lancashire 52. Notifications of diphtheria increased in Lancashire 34 and Northumberland 11 but fell in London 14. The 35 cases of diphtheria notified in Liverpool C.B. were a ninth of the total for the whole country. A new outbreak of dysentery, involving 11 persons, was reported from Southampton, Hartley Wintney R.D. The fall in the notifications of paratyphoid was due to the waning of the outbreak in Yorkshire West Riding; 16 further cases were reported in Sheffield C.B. during the week.

In Scotland the chief features of the returns were increases in the incidence of acute primary pneumonia 69, cerebrospinal fever 12, and dysentery 12. An increase in cases of pneumonia was reported from most areas of the country.

In Eire diphtheria notifications decreased by 17, while a rise was recorded for diarrhoea and enteritis 16, measles 11, and poliomyelitis 11. The 17 cases of poliomyelitis notified during the week involved twelve administrative areas in eight counties. The chief centre of infection is in County Cork, where in recent weeks 17 cases, with 3 deaths, have been reported. The rise in diarrhoea and enteritis was due to the experience of Dublin C.B., where the reported cases rose from 33 to 52.

In Northern Ireland the incidence of measles in the outbreak in Belfast C.B. declined by 9.

Week Ending November 16

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,293, whooping-cough 1,696, diphtheria 330, measles 4,382, acute pneumonia 625, cerebrospinal fever 30, dysentery 70, acute poliomyelitis 15, paratyphoid 26, typhoid 7.

Medical News

Abstracts of World Medicine and Abstracts of World Surgery, Obstetrics and Gynaecology will make their first appearance in January, 1947. These two new journals are being published monthly by the British Medical Association, the first at an annual subscription of 3 guineas and the second at 2 guineas. Applications for subscription should be sent to: The Publishing Manager, British Medical Journal, B.M.A. House, Tavistock Square, London, W.C.1.

A joint meeting of the Society of Public Analysts and other Analytical Chemists and the Food Group of the Society of Chemical Industry will be held at the Chemical Society's rooms, Burlington House, Piccadilly, W., on Wednesday, Dec. 4, at 6.30 p.m., when there will be a discussion on "The Application of Statistical Methods to Food Problems."

Dr. H. L. Marriott will deliver the Croonian Lectures on Tuesday, Dec. 3, and Thursday, Dec. 5, at 5 p.m., at the Royal College of Physicians of London, Pall Mall East, S.W.1. Subject: Some Quantitative Considerations Regarding Depletion of Tissue Fluid and Blood Constituents.

At a clinical meeting of the Medical Society of the L.C.C. Service at 3 p.m. on Thursday, Dec. 5, at the North Eastern Hospital, St. Ann's Road, South Tottenham, cases will be demonstrated in the wards, and Dr. E. H. Harries will give an address on "The Modern Fever Hospital."

The 254th meeting of the Biochemical Society will be held at the National Institute for Medical Research, Hampstead, N.W., on Friday, Dec. 6, at 1.30 p.m., when papers will be read.

Dr. Denis Williams will deliver a lecture on "The Clinical Use of the Electro-encephalogram" before the Whipps Cross Hospital Medical Society at the hospital on Friday, Dec. 6, at 8.30 p.m.

A Doctors' Messages Bureau has recently been set up in Liverpool. When a subscribing doctor is out it takes messages from his patients, and either relays them to an address given by the doctor or retains them until he telephones to notify his return home. Members of the staff are on duty day and night, and have had previous training as signal operators or receptionists.

A special open meeting, arranged by the Royal Anthropological Institute, will be held at the Royal Society's Rooms (Burlington House, Piccadilly, W.) on Tuesday, Dec. 3, at 5.30 p.m., when Prof. R. A. Fisher, F.R.S., will discuss "The Present Position of the Rhesus Blood Group Factor."

At a meeting of the London Association of the Medical Women's Federation in the Hastings Hall of B.M.A. House on Friday, Dec. 6, at 8.30 p.m., Dr. W. Ritchie Russell will speak on rehabilitation after head injuries. Coffee at 8.15 p.m. in the Common Room. Men and women guests invited. On Tuesday, Jan. 7, Dr. Innes Pearse will speak on the Peckham Health Centre.

The Benjamin Ward Richardson Lecture will be delivered at the Royal Sanitary Institute (90, Buckingham Palace Road, S.W.) by Prof. Harold Burrow on Wednesday, Dec. 11, at 2.30 p.m. His subject is "Future Control of Abattoirs and Knacker Yards."

On Nov. 18 a deputation representing all sections of the medical profession in Scotland submitted their views on the National Health Service (Scotland) Bill to the Secretary of State for Scotland, Mr. Joseph Westwood, M.P., at a conference held in St. Andrew's House, Edinburgh. Dr. Wilkie Millar, former chairman of the Scottish Committee of the British Medical Association, led the deputation, and Mr. Westwood promised to consider the points raised. Some time ago he agreed to meet representatives as soon as the Bill was published. Later, the Secretary of State met representatives of the British Hospitals Association, and on hearing their views he gave a similar undertaking.

The Canada Club last week held a dinner in honour of Mr. Norman Robertson, High Commissioner for Canada, Lord Greenwood being in the Chair. Among those present were the following members of the medical profession: The Rt. Hon. The Viscount Addison, Sir Wilson Jameson, Dr. P. L. Backus, Mr. J. Lyle Cameron, Dr. Hugh Clegg, Dr. J. R. M. Collic, Dr. H. Neil Collier, Dr. T. F. Cotton, Dr. T. M. Creighton, Dr. H. A. C. Gregory, Dr. A. Livingstone Johnson, Dr. P. A. H. King, Dr. I. D. MacDonald, Dr. R. S. MacLachy, Mr. Rodney Maingot, Dr. F. H. Mather, Dr. Donald Paterson, Dr. Clarence Routley, Dr. Clive Shields, Dr. Leo Zealand.

The Minister of Labour and National Service, on Nov. 13, inspected one of the mobile exhibition vans which is to be used in the forthcoming recruitment campaign for nurses. The vans will visit villages and smaller towns and will be staffed by technical nursing officers of the Ministry who will co-operate with local hospitals in the areas visited. During the next month a tour will be made of the Southern and South-western Regions in the neighbourhood of Reading and Salisbury.

At a special general meeting of members and honorary members of the Victor Chetwynd Tuberculosis Fund for Allied Ex-Service Men on Oct. 23 it was reluctantly decided to close down the Fund. Applications had been made to various Ministries for official recognition but without avail, consequently the financial support necessary for the Fund's operations had not been forthcoming. The tragic death of the Foundress, Lady (V.B.) Chetwynd, in the air disaster at Le Bourget on Sept. 4 had a serious repercussion on the Fund to which she had devoted so much time and energy.

The Department of Scientific and Industrial Research is sending a team to the Antarctic, under the leadership of Dr. R. A. M. Case, to study the possibilities of using lean whale meat for human food. The proteins of whale meat are believed to be of exceptional value for growth in comparison with the meat proteins of land mammals. Problems of selection, transport, and storage of the meat will be investigated. The expedition, which has been made possible by the collaboration of United Whalers, set sail a month ago in the new factory ship "Balæna."

It has been agreed by the Court of Governors of St. Peter's Hospital for Stone, Henrietta Street, W.C., that the title assistant surgeon to this hospital be abolished and in future all the honorary surgical staff be entitled honorary surgeons.

The Anaesthetics Committee, jointly appointed by the Medical Research Council and the Royal Society of Medicine, has been reconstituted with the following membership: Dr. C. F. Hadfield (Chairman), Prof. F. H. Bentley, Dr. C. Langton Hewer, Mr. R. Vaughan Hudson, Dr. H. King, Prof. R. R. Macintosh, Dr. F. C. MacIntosh, Dr. M. D. Nosworthy, and Dr. G. S. W. Organe (Secretary).

The Department of Ophthalmology of the George Washington University School of Medicine, Washington, D.C., U.S.A., announces that the tenth annual postgraduate course in ocular surgery, pathology, and orthoptics will be given from Jan. 27 to Feb. 1, 1947, and that the William Thornwall Davis intensive postgraduate course in ophthalmology will be resumed during the week Feb. 3 to 8, 1947, when subjects of clinical interest to the practising physician doing eye work will be presented. Further details of the two courses may be had on application to the secretary, Suite 34, 1801, K. Street, N.W. Washington 6, D.C., U.S.A.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Antilog Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proof are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.) TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate, Westcent, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra, Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Massive Doses of Penicillin

Q.—A recent brochure states that 500,000 units of penicillin given intramuscularly to the ambulant case maintains an "effective blood level" for eight to ten hours, and suggests that this dose might be injected every twenty-four hours, or a dose of 200,000 units every twelve hours. This would appear to be in conflict with the findings of Fleming, Young, Suchet, and Rowe (see "Pharmacology of Penicillin" by L. P. Garrod). To quote Garrod: "It is clear that dose and duration of effect are not directly proportioned . . . the greater the magnitude of the dose the less is the prolongation achieved by any given addition to it . . ." Which of these views is correct?

A.—This is an exceedingly important question at the present time, since the "massive dose" system is being increasingly resorted to in order to facilitate the treatment of ambulant patients, both in general practice and in the out-patient departments of hospitals. The facts are as stated in the *Pharmacology of Penicillin*. A blood penicillin level sufficient to inhibit the growth of the standard staphylococcus was found by McAdan *et al.* (*Lancet*, 1944, 2, 336) to last for between one and two hours after doses of 10,000 and 15,000 units; for between two and three hours after 25,000 or 50,000 units; and for rather over three hours after 100,000 units. We know of no comparative published data for larger doses than this, but in a recent personal observation a dose of 250,000 units produced a bacteriostatic blood level up to the fourth hour but not the fifth. It is quite clear that doubling this dose would not be expected to double the duration of effect.

Whatever precise figures be accepted, it is common ground between the advocates of massive infrequent doses and anyone who may oppose this policy that the patient so treated has insufficient penicillin in his blood for a substantial period before the next dose is due—actually for well over half the interval between doses if the doses mentioned are given. The system is also unquestionably extravagant. Against this is to be set the advantage of the exceedingly high concentration attained in the blood shortly after the massive dose is injected. This is said to promote diffusion from the blood into the infected area. I will certainly do so if active exudation is going on. Florey, M. E., Turton, E. C., and Duthie, E. S. (*Lancet*, 1946, 2, 40) have found that after an intramuscular dose of 100,000 units penicillin can be detected in the exudate of a wound for eight and sometimes for twelve, hours. Whether the same result would follow in a closed lesion into which exudation is less profuse is doubtful. The respective advantages of the wide fluctuations in blood level produced by injections given even at three-hourly intervals and the low but constantly adequate level resulting from continuous infusion are still unsettled. Whether doses given only twice or even only once a day are effective is a question which could be studied by animal experiment, but before such a policy is finally accepted it should also be submitted to the most careful clinical study. Such studies so far as we are aware, have not yet been reported.

Car Sickness in Children

Q.—What is the best prophylactic treatment for travel sickness in a child aged 6 during a journey by car?

A.—In the long run, getting used to the mode of travel seems the only satisfactory remedy. Many children are very

ck when they first begin to make car journeys and then appear to get over the trouble. If it is at all persistent, careful examination of the eyes should be made and refractive errors corrected. There does seem to be a visual factor in some instances, and the child is better sitting high up to get an unrestricted field of vision. Some children are helped by sugar. Before the war a well-known brand of glucose (and sodium bicarbonate) tablet was found useful by many parents, but it is unobtainable now. Personal points permitting, plain boiled sweets might be prescribed instead and sucked throughout the journey.

Dental Anaesthesia after Coronary Disease

Q.—A man of 47 recently recovered from an attack of coronary thrombosis. He must now have all his teeth extracted, and the condition of his gums precludes the use of a local analgesic. What general anaesthetic should I advise?

A.—As the man has recovered, the anaesthetic risk is scarcely greater than normal. Nasal nitrous oxide-air or nitrous oxide-oxygen would be suitable. If anginal symptoms are present it would be wise to ensure a smooth anaesthesia by injecting just sufficient thiopentone to abolish consciousness. The patient should be sitting in the dental chair with the mouth prop already in place, and the anaesthetic should then be continued with nasal nitrous oxide-oxygen in the usual way. In this particular case the patient should also rest for half an hour to an hour before going home.

Intestinal Parasites in Dogs and Children

Q.—A seemingly healthy dog, in spite of treatment, continues to pass from time to time scattered, living, single segments of tapeworm. Is there any risk to children living in the same house?

A.—The tapeworm segments are probably those of *Dipylidium caninum*, a common intestinal parasite of dogs and cats. The infection is acquired only through the ingestion of adult fleas or dog lice (*Trichodectes canis*) containing the larval form of the tapeworm. Because of this method of transmission, human infections are relatively rare and mainly occur in children. In the event of such infection the proglottids will first appear in the child's faeces some three to five weeks after the ingestion of the infected insect.

Pantothenic Acid

Q.—Pantothenic acid is said to be a cure for "burning feet" and "jittery legs." What is the dose and in what form is it prescribed?

A.—"Burning feet" and "jittery legs" are stated to be symptoms of vitamin B deficiency, but it is not certain which component of the vitamin B complex is responsible, although riboflavin, nicotinic acid, and pantothenic acid have been suggested. Pantothenic acid can be administered in the form of a powder in doses of 20 to 100 mg. a day. It may also be administered parenterally in doses of 100 mg. So far as is known it is not harmful in these doses. Dogs and monkeys will tolerate a dose of 1 g. per kg. of body weight over a long period.

Treatment of Tetanus

Q.—Would you discuss the value of curare, spinal analgesia, injections of magnesium sulphate, the sulphonamides, and penicillin in the treatment of tetanus?

A.—During the last eighty years curare was used from time to time in treating cases of tetanus, but it was always difficult to assess the right dose. Some preparations were liable to give rise to respiratory spasm, which is extremely dangerous in tetanus. Now that standardized preparations of curarine are available they can be used with caution for controlling the spasm, but this treatment is still in the experimental stage. It should be remembered that treatment with curarine is only symptomatic, and does not affect the course of the disease except in so far as it prevents exhaustion. Even if the spasms could be completely controlled throughout the disease the patient would still die if a lethal dose of toxin had reached the nervous system. The problem of the use of curare and

curarine in tetanus might be well worth considering in an academic discussion.

A spinal analgesic is better avoided in tetanus because of the difficulties of lumbar puncture and its liability to excite reflex spasms. General muscular spasms and convulsions are better controlled by basal anaesthesia, intramuscular paraldehyde, or paraldehyde or avertin given rectally.

Injections into the muscles of concentrated solutions of magnesium sulphate for the prevention of spasms have been abandoned because spasm is better controlled by modern sedatives. Sulphonamide and penicillin therapy are of value in preventing tetanus in so far as they prevent infection in wounds and therefore limit the production of tetanus-toxin. There is no trustworthy evidence that the sulphonamides or penicillin have any effect on the actual toxin once it is producing its effect on the nervous system, or that the course of the disease in carefully controlled cases is modified. Sulphonamides and penicillin have a use in preventing coincident infections, such as pneumonia, developing during the course of tetanus. As this is a real danger in severe cases both may be worth a trial.

Effect of Pus on Sulphonamide Activity

Q.—Is it correct to say that no sulphonamide has any action in the presence of pus, or are there exceptions to this generalization?

A.—The bacteriostatic activity of most sulphonamides is much interfered with by the tissue breakdown products in pus. It is not entirely abolished, but it is so diminished that only highly sensitive organisms are affected. Thus it has been found that under otherwise favourable conditions—notably in accessible superficial infections, as in the case of infected burns—treatment with sulphonamide powder will usually suppress haemolytic streptococci, which are the most sulphonamide-sensitive bacteria concerned in sepsis, but other species are little affected. The only exception to this statement is "marfanil" (*p*-sulphonamidobenzylamine), the activity of which is unimpaired by pus. The efficacy of local treatment with this compound has not yet been adequately studied.

Pseudo-hypertrophic Muscular Paralysis

Q.—What treatment do you advise for a child of 2 years with pseudo-hypertrophic muscular paralysis?

A.—The only treatment which has been shown to have any effect in muscular dystrophies is glycine, of which 10 g. daily would be a suitable dose for a child of this age. On this treatment there is temporary improvement in 50% of cases and occasionally prolonged arrest of the condition. Sometimes, however, when glycine has been given its discontinuance is followed by a deterioration which is more rapid than was the course of the disease before treatment. Glycine appears to be more effective in females than in males. Vitamin E is of no value.

Amphetamine Sulphate in Narcolepsy

Q.—How is amphetamine sulphate used in a case of narcolepsy with cataplexy?

A.—Amphetamine sulphate is given in doses of 5 to 10 mg. several times a day, as may be necessary, to control the sleepiness and cataplectic attacks. The last dose should not be given later than tea-time in order to avoid interfering with nocturnal sleep.

Oestrogens at the Menopause

Q.—Has stilboestrol in a dosage of 1 mg. three times a day always the effect of making a menopausal patient sick?

A.—Stilboestrol often causes nausea and vomiting, but provided it is given in reasonable dosage it more often does not. The occurrence of such toxic symptoms during oestrogen therapy depends on several factors: (1) Individual idiosyncrasies. (2) The sex of the recipient, men being much less susceptible than women. (3) The age and physiological condition of the woman receiving treatment. Young girls generally tolerate it well whereas women of menopausal age are especially sensitive. During pregnancy, and usually during the puerperium as well, oestrogens never cause vomiting even if administered in large doses. (4) The type of preparation used and its dose. There is some evidence that in non-pregnant women at any rate

the more potent the preparation the more likely it is to cause vomiting. The synthetic oestrogens, and especially stilboestrol, are very prone to produce toxic effects. Natural oestrogens, such as oestradiol and oestrone, practically never give rise to untoward symptoms. If synthetic oestrogens are to be used, substitutes for stilboestrol are hexoestrol and dienoestrol, both of which are less liable to produce vomiting. If these are not satisfactory then natural oestrogens should be employed.

For the treatment of menopausal symptoms, however, 1 mg. of stilboestrol three times a day is far too big a dose, and apart from causing vomiting it will have other undesirable effects, such as the production of endometrial hyperplasia and heavy uterine haemorrhage, etc. Given preferably in divided doses of 0.25 mg. or 0.5 mg. a day should be quite adequate—indeed there is much to be said for using small amounts of natural oestrogens rather than synthetic products. In either case the dose has to be carefully controlled and varied, and for the details reference should be made to replies to questions in the *Journal* (1944, 1, 171; 1945, 2, 35; 1945, 2, 307) or to *Gynaecological Endocrinology for the Practitioner* by P. M. F. Bishop (1946, E. & S. Livingstone, Ltd., Edinburgh).

INCOME TAX

Retirement on Falling Income

"CONSULTANT" points out that if he retires by gradually reducing his work the fact that his earnings will be assessable on the basis of the previous year means that he will during such a period be assessed each year on a greater amount of income than he is actually making. He asks whether there is any possibility of getting his "assessment based on the actual income of the year in which the tax is payable."

* Tax on such earnings is payable half in the January of the year of assessment and the balance in the following July; we assume that "Consultant's" inquiry is directed to reconciling these two payments with the profits of the year of assessment. There are two possibilities which should be considered. (a) If the actual earned income is not more than four-fifths of the earned income on which tax is payable a claim can be made for such an adjustment as will result in tax being payable on the actual earned income. But there is an important condition attached to this concession—i.e., that the fall in the income must be due directly or indirectly to the war. Possibly the contention that gradual retirement had been hastened by war strain might suffice. Also the relief has been given for the recent and present year but may not apply to future years. (b) On complete cessation of work "Consultant" will be entitled to have the tax payable for the financial year in which he retires adjusted to the tax on his actual profits of that year—e.g., if he gives up practising as from Dec. 31, 1947, the assessment for the months April–December, 1947, could be reduced to nine-fifths of his earnings for the year to Dec. 31, 1947.

Cost of Typewriter

C. D. is serving with the R.A.M.C. He has bought a second-hand typewriter and expects to sell it and buy a new model next spring, by which time he will be demobilized. Similar transactions will be effected as regards provision of a car. What can he claim?

* In the first place it is most unlikely that the income tax assessing authorities could be persuaded that either the typewriter or the car is "necessary" in the performance of C. D.'s duties in the R.A.M.C., and no allowance will accordingly be made against his Army pay. When he resumes civil practice he will be entitled to depreciation allowance in respect of the car (an initial allowance if the car is bought after resumption) but not in respect of the typewriter—typewriters being regarded as "implements, utensils, or articles employed for the purposes of the profession" rather than "machinery or plant."

Deduction for Use of Premises

A. B. occupies large premises which were formerly used as a nursing home. Several of the rooms are not even in occasional use. The inspector of taxes claims to reduce the proportion of the rent or annual value regarded as applicable to the professional use of the premises from one-half to one-third.

* Prima facie A. B. seems to be justified in pressing for allowance of one-half. The basic question is not what floor-space is available for the two respective purposes but what is a fair division of the rental, having regard to the relative advantages of the premises residentially and for professional use. Further representations might be made to the inspector of taxes coupled with an intimation that if the old ratio is disturbed the point will be taken to appeal before the District Commissioners.

LETTERS, NOTES, ETC.

International Association of Hospital Librarians

The International Guild of Hospital Librarians held its fifth conference in Paris in 1936, its second and last in Berne in 1939. A third conference was planned for London in 1940 but never took place. It will be remembered that in 1936 there was no definite organization of the International Guild, which consisted mainly of individual subscribers and of two national sections—the British and the French. The Order of St. John in Jerusalem and the British Red Cross Society have now formed a joint committee to administer certain funds which remain as a result of collections made during the war. This joint committee has taken over the Hospital Library Department of the Red Cross at St. John and it also publishes a bulletin. Meanwhile, the Guild of Hospital Librarians, whose membership is now purely British, continues its work and publishes the *Book Trolley*. From letters and personal contacts it is clear that an exchange of information and suggestions would be widely welcomed. There still seems to be a need for a forum open to all concerned. Mrs. M. E. Robert, hon. sec. of the former I.G.H.L., is anxious to get in touch with hospital librarians, doctors, and others who are interested, either by personal contact in London or by correspondence, which should be addressed to the International Association of Hospital Librarians, British Medical Association House, Tavistock Square, London W.C.1.

Blanching and Blushing Baby

Dr. MYLES SHELLY (Waterford) sends the following query: delivered a female child eight weeks ago. It was an easy low force delivery with no pressure marks of any sort on baby. The day after delivery the nurse in charge drew my attention to the following facts: (1) When the child was on its back it appeared quite normal. (2) On turning the child on either side, within a few seconds the uppermost half of its body from its scalp to a point just below the xiphisternum became quite blanched, while the side on which the child was lying became engorged and scarlet in colour, the middle of the upper half of the body being the definite line of demarcation. No respiratory or cardiac distress was noticed in whichever position the child was laid. (3) When the child was laid on its back the colour became normal again within a few seconds. The child's heart and lungs were investigated by four other doctors as well as chest x-ray, but nothing abnormal could be found. The child now being eight weeks old, these phenomena have completely disappeared. I would be very glad of an opinion as to the possible cause.

Antimalarial Drugs

Dr. RYAN MACMAHON (Chobham) writes: The answer to I. C. S. P. Hamilton's query (Oct. 26, p. 638) may be discovered in the fact that numerous drugs and substances are not up to sample—e.g., an airtight tin of pyrethrum powder, used for experimental purposes, gave me such excellent results that it was found possible to dispense with mosquito nets; elsewhere pyrethrum powder was denounced as worthless. The explanation in this case was that the latter powder had been stored in open drums or sacks, and had thereby lost its efficacy. Similarly, certain antimalarial drugs have fallen into disfavour because their wartime substitutes have been inferior imitations. Dr. Hamilton's remark that antimalarial "results differ so much in different countries, and even zones" goes far towards answering his own question.

Varicose Veins

Dr. SARA FIELD-RICHARDS (Freshford) writes: I am delighted to see that at last attention has been drawn to the immense importance of varicosities to the community. Mr. Rowden Foote (Nov. 10, p. 680) calls attention to the fact that 10% of the hospital admissions throughout the war were due to this prevalent disease. It was not war injuries and the common ailments of mankind with which our hospitals had mostly to contend, but with this much neglected condition of varix. Anyone who, like myself, has been in general practice for many years and has realized that 10% of my patients suffered from a varicose condition, either minor or major, must appreciate how totally inadequate hospital arrangements are for the specialized treatment. I hope Mr. Foote's letter will do some good to the community in calling the attention of hospital administrators to the crying need for specialized clinics.

Correction

Dr. D. E. SANOS writes: I regret to state that owing to a typing error the word "psychotic" has been wrongly inserted instead of "psychiatric" in line 12 of my letter in the *Journal* of Nov. 23 (p. 793). Since such a word makes no kind of sense with the preceding lines I shall be very grateful if you are able to publish a correction.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 30 1946

HEARD AT HEADQUARTERS

Financial Hardship Committee

The first problem before the Financial Hardship Committee concerns the liabilities likely to be incurred by practitioners, especially when the practitioner has taken a loan which carries an obligation not to relinquish his practice work. It is not easy to ascertain to what extent practitioners are presently indebted to financial organizations. In 1944, when ways and means of assisting practitioners to purchase practices were under consideration, it was estimated that about three and a half millions was on loan to practitioners through insurance companies. Loans arranged through the Medical Insurance Agency since the beginning of the year under the scheme sponsored by the British Medical Association amount in the aggregate to nearly £600,000.

Complete Returns Wanted

A few panel committees—very few in relation to the total number—failed to send in return for the meetings held to consider the Insurance Acts Committee's recommendation on the resignation issue. Although over half of the practitioners whose votes were recorded at meetings of otherwise pledged wholehearted support of the recommendation, the returns were frustrated by the failure of these few committees. It is likely, of course, that the same body of support was forthcoming from those areas as from the others for statistical purposes this cannot be assumed. The committees which failed to send in returns were principally committees in rural areas, and nearly half of them, as it happens, in Scotland. The committees have now received a letter from the chairman of the Insurance Acts Committee pointing out that although for the time being the resignation issue has been shelved, the Committee is still anxious to know, for its guidance in any future action, the full extent of the support it would have received for its recommendation.

Civil Servants

A recent note in this column which implied, on the basis of a definition given in Murray, that the term "Civil Servants" included teachers in State schools is challenged in an amusing private letter to the Secretary from a local government officer who points out that the Civil Service and the local government service are quite different things, that teachers are not even indirectly employed by the central government, which has either the power to appoint them nor to sack them, and whose control is limited to the approval of their basic qualifications and to paying grant on their salaries. It is true, as he adds, that many members of the medical profession would regard becoming local government servants as one degree worse than becoming Civil Servants, but it is better to keep the two things separate.

An Empire Committee

With the growth of the Association overseas (in spite of the fact that the South African Branches have recently detached themselves and formed an affiliated Association of their own) has been felt in some quarters that the Dominions Committee should be enlarged and given new functions. This has been one of the smaller committees of the Association, consisting of members who for the most part have seen service in the Dominions or Colonies or dependencies, but it has done some

extraordinarily useful work and has been of great service to Overseas Branches, especially in matters affecting terms and conditions of service of practitioners employed overseas. One proposal is for an extension of its functions into an Advisory Empire Committee on which each Dominion and India would be represented. It is suggested that it should set up a central bureau in London and, in conjunction with the offices of the High Commissioners, give advice, information, instruction, and hospitality, as well as facilitating educational work—especially postgraduate—the interchange of teachers, the organization of lecture tours, and so forth. There are more than fifty Overseas Branches of the Association, and the Canadian Medical Association and the Medical Association of South Africa are affiliated.

A National Formulary

The B.M.A. and the Pharmaceutical Society have a joint committee which has been discussing the desirability of a National Formulary for the purpose of a National Health Service. The necessity for a Formulary is not agreed as between the two sides of the table, but it is generally assumed that there will be a continuation of the National Formulary in some shape or other, and, that being so, one standard Formulary of national application and suitable to all branches of medicine is agreed to be desirable. Both the organizations concerned are recommended by the joint committee to give consideration to the need for a standard Formulary based on the formulary section of the *British Pharmaceutical Codex* and compiled by a joint committee of members of the medical and pharmaceutical professions.

Liaison with Industrial Medical Officers

The Association of Industrial Medical Officers has assented to the terms of an agreement recently approved by the B.M.A. Council whereby proposals concerning medico-political policy will be communicated before action is taken, and if the proposals are agreed by both bodies the necessary action will be taken by the B.M.A. There is a provision for mutual representation at meetings.

Pathologists at Mental Hospitals

The London County Council is experiencing difficulty in obtaining candidates with appropriate qualifications and experience for appointments as assistant pathologists in the laboratories of its mental hospital service. It is therefore proposing to establish a scheme for the appointment of junior assistant pathologists—similar to that already established in the general hospital laboratory service—who will be interchangeable with assistant pathologists within the limits of the fixed staff, and when duly qualified by not less than four years' experience, both clinical and pathological, will be eligible for promotion to the higher positions. The basic salary for the new grade of junior assistant pathologist will be £650, rising by increments of £25 to £725 a year, and the basic salary of the assistant pathologist is £900, rising by increments of £50 to £1,100.

The Ministry says "No"

The Insurance Acts Committee a month or two ago made a request to the Ministry of Health that doctors should be given priority in the supply of refrigerators for the economic preservation of penicillin and other drugs. The Minister, however, feels that no strong case for this has been made out. Storage in a cool, dry place is sufficient for dry penicillin and

its non-aqueous preparations, while as to the aqueous preparations, these will not keep for more than a day or two even in a refrigerator. Apart from that, there is the serious shortage in the supply of refrigerators for houses. Another representation to the Ministry, which has also been refused, was for the inclusion in the schedule of appliances of a preparation of sterile petroleum jelly gauze. The Ministry feels that this is not an opportune moment for extending the schedule except in matters of definite urgency.

Domestic Help for Doctors

It is difficult to say how far the domestic help situation has improved by the cessation of war work for women. In some localities matters appear to be rather worse than they were during the war, when the Ministry of Labour and National Service had comprehensive control of female labour through the National Service Acts, and there was some priority for doctors' service in the matter of direction. In other places relief has been vouchsafed to overworked doctors' wives by women who find service in a doctor's household a pleasant relief after employment in factories and canteens. The officials of the Ministry now have only persuasive powers.

One source of relief may be afforded by Irish maids. In this connexion it is worth noting that the travel control arrangements between Eire and Great Britain have been substantially modified, and employers are now free, so far as the Ministry is concerned, to make their own arrangements for the employment of such women. As for Continental labour, if a practitioner knows of any individual foreign national (other than German) who is willing to take domestic employment in his household he should apply to the Ministry of Labour, International Labour Branch, Norfolk House, St. James's Square, for advice. He would be required to accept responsibility for the travelling expenses incurred both in bringing the woman to this country and in her return should she wish to go back.

Correspondence

National Health Service

SIR,—The profession is to be congratulated upon having induced Mr. Bevan to recant his early folly of refusing to apply the Spens Report to remuneration under the National Health Insurance Service. Doubtless he would have preferred to reserve some of our financial rights to garnish his new service, but it is right not only that a Minister should honour his pledges, but also that both the old and the projected services should be judged and administered on their own merits. In the same way it is important that we should on all future occasions insist that the Spens Report or some such independent standard be applied to maintain an adequate level of remuneration. I have previously pointed out the dangers attached to a fixed capitation rate, and in my opinion no rate should be accepted in future unless it is fixed by the constant or periodical application of some standard that compensates for such factors as monetary depreciation, falling population, and increasing numbers of medical men. Failure to secure any such machinery accounts mainly for the injustices so long endured and unanimously condemned by insurance practitioners.

There are other lessons to be learnt from our recent experience. First, that it is ridiculous to assert that the medical profession can never stand together. Possibly Mr. Bevan misjudged us there. In fact we always have been united over the subject of N.H.I. remuneration and have given no one reason to suppose we could not act in a concerted fashion. However, some people are talking as if the profession had just achieved a new cohesive force that could be turned against the Health Service measure to redress at the eleventh hour the outcome of past divided counsels. The truth is not that the profession lacks the ability to follow or back its convictions, but that, like all free men, it refuses to be regimented into a semblance of unity in relation to a mass of highly controversial matter in order to dictate the views of one section of opinion.

All along our leadership has made the great mistake of attempting to secure unanimity and support for a sort of blun-

derbuss or comprehensive opposition to health legislation, even when this was proposed by a comparatively mild Government. A fair amount of support and more lip service has been forthcoming, but I doubt whether there is any decisive body of conviction such as was rallied to support our N.H.I. claims. To one unbiased effort to ascertain the views of the profession was ignored, yet in those questionnaires somewhere under the dust still lie the ungerminated seeds of real unity. A sincere and responsible body of conviction could have been developed from this with subsequent adjustment and further secret balloting—worth more in the end than all the veiled regimentation into official policy that has gone on at many meetings. We should all have had to be content with much less than an extremists might desire, but I venture to suggest that we should soon have achieved a really inspired and effective unity in some important respects. While we were contemplating attack upon an impossibly wide front, Government circles were profiting by a perusal of the questionnaire: the very reconnaissance of our own situation upon which we should have built up our policy.

Let us hope that we can still secure a few important advantages by a last-minute recognition that these might accrue in a general spirit of co-operation. I believe that a majority of the profession is not convinced that it would be either good policy or good sense to refuse to negotiate with H.M. Government at this stage. No harm can come of it, while, as I have suggested some good might still ensue. Moreover, a pigheaded refusal even to enter into non-committal discussion would further forfeit public sympathy.—I am, etc.,

Eye, Suffolk.

J. SHACKLETON BAILEY.

SIR,—The Health Service Bill, Clause 34(1), provides that every medical practitioner, other than a paid assistant, who wishes to provide general medical service shall be entitled, on making an application at any time before the appointed date in the prescribed manner, to be included in the lists of medical practitioners.

There must be many others like myself, recently demobilized from the Forces, who have families and who for one reason or another have not practices of their own and are now acting as assistants. Are we, under the new scheme, to continue to be employed as assistants? If so, how are we eventually to achieve the status of "principal" in the Service?—I am, etc.

EX-SERVICE ASSISTANT.

SIR,—A point in connexion with the provisions of the National Health Service Act dealing with sale of goodwill seems to me to need elucidation. If a practitioner has both private and insured patients it should be quite clear that the penalties in connexion with sale should apply to the latter. Further, if his house and surgery are used for both private and insurance practice, how do the provisions about sale of the same affect him or his widow? Why make those vexatious regulations about the sale of house property anyhow?—I am, etc.,

London, S.E.5.

F. JOYCE.

Demobilized Medical Officers

SIR,—A friend of mine was recently appointed house physician to an important and well-known provincial voluntary hospital of approximately 350 beds. He informs me that he was selected out of about 70 applicants for the post. The resident staff of the hospital consists of 13 officers and includes only 3 ex-Servicemen (including himself). Of the remaining ten no less than seven are women, including one Central European refugee.

I am all in favour of the competition of women on an equal basis with men, but as these posts are on a six-monthly basis such a state of affairs in 1946 does savour strongly of discrimination against ex-Servicemen. Is this attitude common among hospital committees? This subject might form an interesting and instructive line of research to anyone with the time and inclination to collect data from hospitals throughout the country.—I am, etc.,

Bourne End, Bucks.

A. G. S. BAILEY.

At the annual meeting of the St. Helens (National Health Insurance Committee) Dr. D. Campbell, M.R.C.P., was appointed chairman for the twelfth consecutive year.

B.M.A. LIBRARY

The following books were added to the Library during July and August, 1946:

- exander, F., and French, T. M.: *Psychoanalytic Therapy. Principles and Application.* 1946.
- Sh, J. E., and Spitz, S.: *Pathology of Tropical Diseases: Atlas.* 1945.
- iley, H.: *Demonstrations of Physical Signs in Clinical Surgery* Tenth edition. 1946.

Association Notices

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows: an Ernest Hart Memorial Scholarship, of the value of £200, a Walter Dixon Scholarship of the value of £200 and four Research Scholarships, each of the value of £150. These Scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State Medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession. Each Scholarship is tenable for nine months, commencing on Feb. 1, 1947. A Scholar may be re-appointed for not more than two additional terms. A Scholar is not necessarily required to devote the whole of his or her time to the work of the research, but may hold a junior appointment at a university, medical school, or hospital, provided the duties of such appointments do not interfere with his or her work as a Scholar.

Conditions of Award, Applications

Applications for Scholarships must be made not later than Saturday, Dec. 28, 1946, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants are required to furnish the names of three referees who are competent to speak as to their capacity for the research contemplated.

The Katherine Bishop Harman Prize

The Council of the B.M.A. is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1947. The purpose of the prize, which was founded in 1926, is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child-bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1947, but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question will be such proportion of the accumulated income as the Council shall determine. The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed, at B.M.A. House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1946.

GROUP OF DERMATOLOGY

A meeting of the Group of Dermatology, to which all members of the Group are invited, will be held at B.M.A. House on Wednesday, Dec. 18, at 2 p.m.

Members of the Group are invited to forward to the Secretary, B.M.A. House, Tavistock Square, London, W.C.1, suggestions or recommendations for consideration by the meeting.

(Sgd.) C. HILL,
Secretary.

Diary of Central Meetings

DECEMBER

5. Thurs. Publishing Subcommittee, 11 a.m.
11. Wed. Council, 12 noon.

Branch and Division Meetings to be Held

LEIGH DIVISION.—At Boar's Head Hotel, Leigh, Tuesday, Dec. 3, 8.15 p.m. Meeting. Agenda includes show of Sound Films. Main feature: Intravenous Anaesthesia.

NUNEATON AND TAMWORTH DIVISION.—At Red Lion Hotel, Atherstone, Tuesday, Dec. 3, 8.30 p.m. Mr. A. J. Moffett: Sinusitis.

SWANSEA DIVISION.—At Mackworth Hotel, Friday, Dec. 6, Dinner Dance, 8 p.m.

Meetings of Branches and Divisions

PLYMOUTH DIVISION

A dance was given at the Moorland Links Hotel, Yelverton, on Nov. 13. This was the first social event on a large scale held by the Division since the 1938 A.R. Meeting in Plymouth.

PRESTON DIVISION

The B.M.A. Lecture was delivered at the Preston Royal Infirmary on Nov. 12 at 8.30 p.m. by Prof. D. W. Dunlop, of Edinburgh. Dr. A. R. Wood, chairman of the Division, occupied the chair. Prof. Dunlop's subject was "Medical Emergencies"; and for an hour he expounded to an audience of about seventy members new and improved methods of dealing with the emergency treatment of diabetic coma, haematemesis, haemoptysis, bronchial asthma, coronary thrombosis, and a number of other conditions, debunking by the way some traditional methods and drugs. A discussion followed in which many members took part.

A vote of thanks to the lecturer was proposed by Dr. A. E. Rayner, O.B.E., and seconded by Dr. D. M. Anderson. A collection was taken for the Royal Medical Benevolent Christmas Gift Fund, and it realized the sum of £15 10s.

SOUTH-EASTERN COUNTIES DIVISION

A meeting of the Division was held at Galashiels on Oct. 13, 1946. Dr. L. G. Campbell took the chair. He welcomed the Minister's acceptance of the Spens Committee's recommendation under which he had agreed to pay a capitation rate of 15s. as from Jan. 1, 1946.

The secretary pointed out that the Roxburgh Panel Committee had sent a resolution drawing attention to the necessity for an increase in the mileage payment to be in line with the increased capitation fee. He reported that the panel committees of Peeblesshire, Selkirkshire, and Roxburghshire had all received 100% acceptance replies from insurance practitioners in their areas agreeing to the action of the Insurance Acts Committee, while Dr. Campbell reported that three doctors in Berwickshire were not in favour of it but the others were. Dr. McCracken wanted the Insurance Acts Committee to formulate a guarantee that no doctor not accepting would take patients from those who were supporting the Committee. It was left to the representatives to the Panel Conference to take up this matter should it be felt necessary.

Hospital Survey.—The secretary drew attention to the report of the Committee, which had now been published. Dr. McLay suggested that those who had made the report had not spent sufficient time in the various hospitals to give a full opinion of the state of affairs. Drs. Haddon and Glover both spoke of the plans already made for a central hospital at St. Boswells.

Medical Treatment of Evacuees.—Payment had now been made to the secretary for 1945 a few weeks ago. The position was difficult in that many of the evacuees for whom payment had been received were supposed to come from the London and southern areas, and, as the secretary had no idea where in the various counties these evacuees were situated, it was difficult to allocate the money. The Central Medical War Committee was taking the matter up with the local committee, and in a short time it was hoped that they would be able to disburse the money.

The Rural Practitioners Sub-committee had asked each area to give their ideas on: (1) Health Centres. In discussion it was generally agreed that better diagnostic facilities should be provided, and that cottage hospitals in the Borders provided the most suitable location for these. Dr. Pollock spoke of the necessity for ultra-violet rays, radiant heat, bacteriological and other diagnosis, which could be undertaken at these small centres. Dr. Smith criticized cottage hospitals in general and felt that the cases at present dealt with there should be transferred to the larger hospitals. Dr. Allan mentioned that he had four clinics in Berwickshire to try to help

the position. Drs. Balfour, Haddon, and Campbell thought additional facilities at cottage hospitals would be sufficient. (2) Remuneration. The secretary suggested that a 50% increase in mileage payment would about meet the case. Dr. Haddon supported this and it was left to the representatives to the Panel Conference to further this suggestion.

Attention was drawn to the Royal Medical Benevolent Fund.

Scottish Scheme for Protection of Practises.—The secretary had been asked by the Central Committee for a report on the questions involved. This report was read to the meeting.

Dr. Dow spoke on the position at Peel Hospital. They were carrying on there under difficulties with a reduced staff. No payment was being asked for patients and they could be admitted directly by application to him without previous arrangements with the Royal Infirmary. Until some of the chronic cases were discharged there was not a tremendous number of beds available; he hoped that by Christmas it would be much more satisfactory.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—*Tues.*, and *Thurs.*, 5 p.m., Croonian Lectures by Dr. H. L. Marriott: Some Quantitative Considerations Regarding Depletion of Tissue Fluid and Blood Constituents.

ROYAL SOCIETY OF MEDICINE

Section of Orthopaedics.—*Tues.*, 5.30 p.m. (Cases at 4.30 p.m.)

Section of History of Medicine.—*Wed.*, 2.30 p.m. Paper by Dr. H. P. Bayon: The transition between scholastic and clinical Medicine in Europe during the 16th and 17th centuries. (Illustrated by lantern slides.)

Section of Comparative Medicine.—*Wed.*, 5 p.m. Short Papers by Dr. H. H. Holman: Studies on the haematology of the horse, ox, and sheep. Mr. J. B. Brooksby: The serum proteins of the domestic animals. Dr. C. L. Oakley: The normal constituents of human blood. Dr. H. Grüneberg: Inherited disorders of the blood in rodents.

Section of Surgery.—*Wed.*, 8 p.m. A Pathological meeting will be held.

Section of Otolaryngology.—*Fri.*, 10.30 a.m. (Cases at 10 a.m.) Paper by Mr. Terence Cawthorne: Review of surgery of otosclerosis. Coloured film by Mr. Garnett Passe: Fenestration operation. Cases will be shown.

Section of Laryngology.—*Fri.*, 2.30 p.m. (Cases at 2 p.m.) Discussion: Epistaxis. Opener: Miss D. J. Collier. Short paper by Mr. R. G. Macbeth: Ligation of anterior ethmoid artery for epistaxis. Cases will be shown.

Section of Anaesthetics.—*Fri.*, 5.30 p.m. Discussion: Shock, with special reference to anaesthesia. Openers: Prof. H. N. Green and Dr. R. P. Harbord.

FACULTY OF HOMOEOPATHY.—At London Homoeopathic Hospital, *Thurs.*, 5 p.m. Dr. Karl König (Vienna): Work Among Problem Children.

WEEKLY POSTGRADUATE DIARY

BLACKPOOL: VICTORIA HOSPITAL.—*Thurs.*, 8 p.m. Mr. Miller: The Uses and Abuses of Penicillin in Surgical Practice.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, Leicester Square, W.C.—*Tues.*, 5 p.m. Dr. G. B. Dowling: The Erythrodermas. *Thurs.*, 5 p.m. Dr. L. Forman: Cutaneous Manifestations of Malignant Disease.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 16 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

BLOOM.—On Nov. 13, 1946, at Ferncroft Nursing Home, N.W.3, to Edna Bloom (née Satin), wife of Ross Bloom, F.R.C.S., 15, Hocroft Road, N.W.2, a son.—Allan Neil.

COLE.—On Nov. 22, 1946, at The Chase, Roughley, Sutton Coldfield, to Peggy (née Bryant), M.B., M.R.C.S., wife of J. G. L. Cole, M.B., M.R.C.S., a son.—Timothy James.

COONEY.—On Nov. 19, 1946, at the County General Hospital, Otley, Yorks, to Gwyneth, wife of J. A. Cooney, M.B., Ch.B. (R.A.F., Iraq), a daughter.

HARTLEY.—On Nov. 22, 1946, to Bee, wife of B. P. R. Hartley, M.B.E., M.B., Westwood House, Brocco Bank, Sheffield, 11, a son.

MACNAUGHTAN.—On Nov. 17, 1946, at Edinburgh, to Jean (née Wiseman), wife of Dr. I. P. J. MacNaughtan, a daughter.

ENGAGEMENT

TOWNSEND-SPARKS.—The engagement is announced between Eric, younger son of Mr. and the late Mrs. Arthur Townsend, of Skipproo-in-Craven, Yorkshire, and Elizabeth, eldest daughter of the late Dr. and Mrs. John Peel Sparks, of Cullercoats, Northumberland.

MARRIAGE

STONE—MULROY.—On Nov. 9, 1946, at Halifax, Capt. M. C. Stone, R.A.M.C., to Mary Philippa Mulroy, S.R.N.

DEATH

MCGILLIVRAY.—On the night of November 19/20, while working for the Control Commission in Germany, the result of a motor accident, Isabel Margaret (Abelle), M.R.C.P.Ed.

TREATMENT OF BREAST ABSCESSSES WITH PENICILLIN

BY

M. E. FLOREY, M.B.*

Research Clinical Assistant

IN COLLABORATION WITH

J. S. MacVINE, F.R.C.S.Ed., M.R.C.O.G. AND M. A. M. BIGBY, M.D., M.R.C.O.G.

Obstetric Surgeon

Assistant Obstetric Surgeon

Central Middlesex County Hospital

The following account deals with various methods of treating breast abscesses with penicillin. The justification of those methods depended on their results as compared with those obtained from the methods at present employed. For this reason a series of controls was treated contemporaneously with

Several cases examined during the puerperium, with flushed and tender breasts, some pyrexia, but ill-defined induration, were excluded as not giving sufficient evidence of infection. These did in fact clear up without chemotherapy, by the usual methods of elevation of the breast and the application of ice-bags. The distinction, however, was not always easy to make, and one case in which induration was not well defined was included in the controls.

Table Comparing Results in Breast Abscesses

	No. of Cases	Duration in Days after First Treatment of					
		Pyrexia		Suppuration		Healing Time	
		Mean \pm S.E.	S.D.	Mean \pm S.E.	S.D.	Mean \pm S.E.	S.D.
Controls	16*	7.5 \pm 1.97	\pm 7.86	13.8 \pm 3.0	\pm 12.0	26.5 \pm 2.45	\pm 10.17
Treated	18	3.9 \pm 0.91	\pm 3.73	6.3 \pm 0.82	\pm 3.5	13.5 \pm 1.50	\pm 6.37
Difference		3.6 \pm 2.17		7.5 \pm 3.11		13.0 \pm 2.87	

S.E. = Standard error of mean. S.D. = Standard deviation.

* Two control cases excluded, because in Case 1 the follow-up was not conclusive, and in Case 2 the duration of pyrexia was 63 days, suppuration > 88 days, and healing > 119 days.

† Mean of 17 cases only; no record of 18th case.

‡ Mean of healing time of abscesses in 17 breasts.

the penicillin series and the two were compared not only as to the average duration of pyrexia, suppuration, and healing time, summarized in the accompanying Table, but also with regard to a number of other points which were considered important. The apparent advantages obtained by the use of penicillin would seem to justify a detailed description of the methods of administration found most satisfactory.

The survey comprised all cases which came under treatment at the Central Middlesex County Hospital between Nov. 19, 1943, and May 18, 1944. They were nursed in the obstetric or surgical wards according to whether their symptoms arose during the puerperium or later. Both series were cared for by the same nursing staff and the same surgeons. The cases numbered 36, and, in order to eliminate any bias on the part of the investigators, they were chosen for the control or penicillin series in strictly alternate chronological order. There were 22 abscesses in the 18 control cases and 24 in the 18 penicillin-treated cases. Factors which might have favoured one series more than the other were also noted. The time of onset in relation to parturition was within the first fortnight in 6 control and 7 penicillin-treated abscesses, and a further 9 and 7 respectively arose within five weeks of the same date. The incidence in primiparae was half the total in each series. The age incidence was somewhat lower and the onset more often rapid in the penicillin cases, and pyrexia from other causes during the puerperium was present in 4 of the latter. Extraneous factors therefore could not be said to have favoured the penicillin group.

No case was accepted for investigation unless a well-defined, tender, and indurated mass was palpable in the breast tissue.

Methods of Treatment

Controls, with two exceptions, received at least one course of sulphathiazole or sulphamezathine of between 20 and 30 g. This was begun pre-operatively when abscesses were not well localized, incision being carried out later at the surgeon's discretion. When fluctuation could be detected on admission, incisions were made immediately—single for small abscesses and with a counter-incision for larger ones. Drainage was maintained by a corrugated rubber drain or a vaselined-gauze wick for 48 hours. Subsequently the wounds were dressed or irrigated with eusol, and when they became superficial flavine and paraffin or lotio rubra were generally used. A course of stilboestrol varying from 30 to 65 mg. in 3 to 5 days was given to patients who were lactating.

The penicillin cases were treated according to the type of case and, as the investigation progressed, also to the lessons learnt from earlier mistakes. No sulphonamides were given, and stilboestrol was administered to only 3 cases, all in the early stages of the inquiry. The methods are described in detail below.

Items of Comparison

1. *Bacteriological Findings.*—*Staph. aureus* was the only organism found at operation in the abscesses with no external communication. One which had arisen from the residual sinus of an earlier abscess was, however, infected with a haemolytic streptococcus alone. Milk from six infected breasts was examined and found to contain *Staph. aureus* in each instance. The pus from one case in the control series was sterile on culture at operation and revealed no organism but *Bact. coli* in subsequent cultures. It is as well to mention that a phenomenon noticed in other acute infections was also noted here on several occasions—namely, that some swabs taken from pus at the time of the first incision were sterile on culture and yet cultures made later from swabs of the wound walls produced an abundant growth of *Staph. aureus*. Subsequent swabbings were made at weekly intervals in the controls and as soon as pus had disappeared in the penicillin-treated cases—i.e., from the second to the thirteenth day after the first local treatment. In the controls *Staph. aureus* persisted in 18 of 21 abscesses followed up till healing was nearly complete, and disappeared in 18 out of 20 "treated" abscesses before treatment was discontinued. The time of disappearance was anything from the second to the fifteenth day of treatment.

* With a grant from the Medical Research Council

The disappearance of pus from the exudate coincided closely with the disappearance of *Staph. aureus* from cultures. In fact, it was soon realized that in these staphylococcal infections the taking of a swab for culture was simply a way of confirming the clinical finding that the replacement of pus by a sero-sanguineous exudate signified that the abscess walls were no longer infected.

Secondary infection with *Str. haemolyticus* occurred in 3 control cases, the healing times of two of these being prolonged much beyond the average. No penicillin-treated cases became so infected. The remaining secondary invaders—*Staph. albus*, *Micrococcus tetragenus*, *Bact. cali*, and *Proteus*—appeared in 7 control and 5 penicillin-treated series, the Gram-negatives occurring in the same number—2—of each series. No clinical significance could be attached to the presence of these organisms, as they appeared only when wounds were superficial and healing.

2. *Suppuration* seemed to have been prevented by sulphonamide administration in one control case for several weeks, but after discharge from hospital this patient reported again with a painful lump in her breast. Unfortunately she was lost sight of after this. In some instances it appeared that pus formation was prevented or at least reduced by the use of sulphonamides. No frank pus was found in 3 cases. A fourth had a virulent infection in several loculi of one breast which spread later to the other. She received intensive courses of sulphamezathine and sulphathiazole, and pus was found in quantity only at the first incision, subsequent incisions into large swellings revealing only small amounts of sero-pus. In spite of this, however, once pus had formed in an abscess it continued till healing was well advanced. No case treated with penicillin at the stage already defined avoided the formation of pus. In fact, suppuration seemed to be speeded up and, while it localized readily, the pus became much thicker than in any of the control cases. It disappeared quickly, however, so that its average duration was less than half that of the controls.

3. *Twenty-two operations* were performed on 17 of the 18 controls, 5 cases requiring later incisions owing to extension of the infection. In all, 32 incisions were made. There were 4 operations in the penicillin-treated series and 4 incisions.

4. *Pyrexia* at the beginning of treatment varied very much from case to case, being little more than 99° F. (37.2° C.) where abscesses were already well localized, but reaching 103° F. (39.4° C.) in those whose infection arose in the puerperium. There were 5 cases in each series whose initial temperature rose above 101° F. (38.3° C.), the remainder all having milder degrees of pyrexia. The average duration after penicillin treatment, however, was reduced to half that of the controls. This was not because the penicillin-treated cases necessarily reached normal ranges before the controls, but because, once normal, their temperature did not rise again, as happened in several of the latter.

5. *Complications* in controls consisted of secondary abscesses in the same or the opposite breast or in axillary glands in 6 instances, and septic dermatitis in 3; while the infection in one long-standing case spread to the lids and the patient suffered from a persistent blepharitis. In the "treated" series two secondary abscesses developed, both in cases receiving local treatment only. A milk sinus persisted in a third case, prolonging the healing time to that of the average for the controls.

6. *Healing time* was estimated from the beginning of treatment, chemotherapeutic or surgical, till no further dressing or other local treatment was needed. In the case of open wounds or sinuses the end-point was the day on which the wound became quite dry; in abscesses that were aspirated it was the day after the last aspiration on which any fluid could be withdrawn, no further treatment then being required. Where several abscesses were present in one breast the healing time covered the period from first treatment till the last abscess was healed. But if abscesses were present in both breasts their healing times were assessed separately (see Table).

Two patients had to be excluded from the control series—one because, though the induration and pyrexia appeared to subside under sulphonamide therapy, she later reported to the out-patient department with a painful lump in her breast; but thereafter she could not be traced. The second patient had so severe and prolonged a convalescence that her healing time

would have upset any reasonable comparison of the two series. There were no exclusions in the penicillin-treated series. After their abscesses had healed all these cases were followed up for from one to six weeks, according to the severity of the initial lesion. The healing times were therefore considered genuine, and they showed that not only was their average reduced to one-half that of the controls but that only one of all the penicillin-treated cases exceeded the average time for the controls.

7. *Breast feeding* had to be stopped in the majority of controls who were lactating. In the penicillin-treated cases, once confidence in the method of treatment had been gained, the avoidance of stilboestrol gave the mothers every opportunity to continue feeding their babies on the normal breast throughout treatment and to resume with the other after it had healed. In one case suckling was difficult because of retraction of the nipple following a persistent milk sinus, but in others the lack of scarring and retraction was in marked contrast to that of some of the controls. Induration in penicillin-treated cases, especially around those abscesses which were only aspirated, persisted for up to five weeks after treatment was begun; but it eventually resolved, and after this time it was difficult to detect any indication that an abscess had existed.

8. *Days in Hospital*.—A final assessment was made of the days spent in hospital by the two series and also of the period of time during which they had to attend the out-patient department for treatment. These were as follows:

	Control	Treated
Total number of days spent in hospital	348	191
Total period of out-patient treatment	313	41
Total	661	232

Only 4 penicillin-treated cases had any out-patient treatment, though undoubtedly a good part of the treatment all received as in-patients could have been carried out effectively by daily attendance at the hospital. The need for accurate and frequent observation when a new method of treatment was being used, however, impelled their retention until it was possible to claim with assurance that these methods, when systematically used, were not only devoid of serious consequences but gave reliable results.

Methods of Treatment with Penicillin

These depended on the condition of the breast when the patient was first seen. The choice of dose—for systemic or local effect—depended on whether or not the infection was still in the acute spreading stage with attendant constitutional disturbance. The method of treatment depended on whether an abscess had formed and on the amount of pus present.

Intramuscular Injections of 15,000 Units Three-hourly (13 Cases).—These were used for the acute phase before fluctuation could be detected, also when there was much pyrexia and a generalized flush over the breast, and for all infections arising in the puerperium. (Two cases with puerperal abscesses, not so treated initially, demonstrated the necessity for systemic treatment in acutely spreading lesions.) Injections were continued for a minimum of 12 hours, but no case required them for more than 3½ days. An injection was given pre-operatively immediately before any incision or exploration was carried out. The intramuscular treatment was stopped as soon as the pain had diminished, the flush began to fade, the oedema to lessen, and the pyrexia to subside.

Aspiration and Injection of Penicillin under Local Analgesia once in 24 hours (10 Abscesses).—This method was employed as soon as any fluctuation could be detected, and was even attempted without definite signs in deep and small abscesses which appeared to have localized. No spread of inflammation occurred after these explorations, but the patient always had penicillin circulating in her blood stream from an intramuscular injection given immediately before they were carried out. The aspiration was done with a wide-bore needle—a West Middlesex transfusion type containing a stylet was found satisfactory, as the needle could not become blocked before it had penetrated the abscess cavity. The area of maximum redness and swelling was avoided and the needle inserted obliquely from

where the skin was firm. A syringe having been attached to the needle after withdrawal of the stylet, all possible pus was aspirated. A second syringe containing the penicillin solution then replaced that used for aspiration, and an amount was injected equal to two-thirds the volume of the pus aspirated. If no pus was found a small amount of penicillin was injected into the tissues and along the needle track as the needle was withdrawn.

These aspirations and injections did not overlap the intramuscular treatment in any case by more than 24 hours, the assumption being that once pus was localized there was no need for further intramuscular treatment. When any doubt about complete localization existed, and when it was possible to inject a full 24-hour dose without leakage, 120,000 units, made up at the bedside in the required quantity of saline, were injected into the abscess cavity. Such a dose ensured a circulating concentration of penicillin for at least 12 hours (Florey and Heatley, 1945). By this method of systemic treatment three abscesses in one breast received treatment by injections into one only, until all had localized and could be treated individually. Where the abscess was well localized a concentration of 500 units per ml. was quite sufficient to sterilize the infected tissues. If no sinus formed this process was repeated every 24 hours till the pus, which became thicker and more slimy during the first two or three days of treatment, disappeared and was replaced by slimy blood-stained and then sero-sanguineous fluid. On the appearance of a sero-sanguineous exudate a film and a culture were made from the fluid, and if *Staph. aureus* was not present in either no further treatment was carried out. The breast was palpated carefully each day for at least a week and signs of recrudescence were looked for in temperature, flush, tenderness, or increasing induration. There was no recurrence in any of the cases so treated, but it should be remembered that treatment was never considered completed without confirmation of a sterile culture. Abscesses so treated contained no more than 10 ml. of pus and required daily injections for 4 to 7 days, irrespective of whether or not preliminary intramuscular treatment was necessary.

Instillations of Penicillin after Expression of Pus (5 Abscesses).—These instillations were most frequently made through a sinus which formed where the abscess pointed. This occurred very rapidly under the influence of penicillin therapy, and on the 24-hourly-aspiration-and-injection schedule it was often impossible to prevent sinuses developing. They were, however, of considerable value in treating the case, because the abscess cavity could now be emptied twice a day by gentle pressure and instillation carried out as often. In the interval, the mouth of the sinus was covered with cotton-wool soaked in collodion to prevent the egress of solution. Instillations were made by means of a fine rubber tube, nasal or ureteric catheter size, or by means of a West Middlesex needle, the important point being that the tube should completely occlude the mouth of the sinus to prevent escape of the solution during the injection.

A combination of the two methods of local treatment was used in 5 abscesses, instillations being made once a sinus had developed along the track of the aspirating needle. After

FIG. 1.—Treatment by indwelling cannula. Small breast abscess tending to point at c. a: West Middlesex needle inserted obliquely into abscess cavity so as to avoid the area where pointing would occur. b: Layers of gauze dressings held by strapping to secure the position of the needle. Needle and dressings are covered with another sterile gauze dressing in between treatments.

aspiration a West Middlesex needle was left in the abscess cavity and fixed in place under a sterile dressing so that a second evacuation and instillation could be performed by the nursing staff in the absence of the medical attendant (Fig. 1). A sinus developed along this track in a day or two. At each subsequent treatment discharge was first expressed through the sinus, and the needle could then be inserted without local analgesia and by unskilled hands. The disadvantage of sinus formation over aspiration alone was the fact that it added a week to the healing time, but this was offset by the greater comfort of the treatment and the fact that it could be repeated more often, thus getting rid of purulent exudate quickly and so hastening the subsidence of infection.

Instillations Following Incision and Suture (Fig. 2) were used for 4 abscesses, all with large cavities containing 100 to 150 ml. of

FIG. 2.—Treatment by incision and insertion of drainage-tube. Large abscess tending to point at a. b: Rubber tubing inserted through incision line, which has been sutured after evacuation of abscess. c: Syringe containing penicillin solution—the amount being two-thirds of the pus evacuated or not more than 10 ml. d: Adapter for inserting in rubber drainage-tube so as to enable a Record syringe to be used. e: Spigot for closing mouth of tube after injection.

pus. Complete evacuation of the cavity required a good opening—away from the area where the abscess was pointing—but this was then sutured round a rubber tube with an internal diameter of about a quarter of an inch (5 mm.). Providing penicillin was instilled, once pus was fully evacuated from a well-localized abscess it did not form in quantity again, and the emptying of the discharge through the tube could then be achieved by gentle pressure. This modified method of drainage was a great deal more satisfactory than aspiration if an abscess contained more than 10 ml. The patients preferred instillations to intramuscular injections or aspirations and injections, for they were almost painless. There was the added advantage that they could be carried out by the nursing staff at more regular intervals than are generally possible with the medical attendant. These abscesses required treatment twice daily for from 4 to 8 days when well localized. Though this method alone cleared up a virulent spreading infection in 15 days, subsequent cases treated with preliminary intramuscular injections till localization had occurred improved more quickly. The choice of local (500 units per ml.) or systemic dose (120,000 units in 24 hours) was governed by the same considerations as have been discussed already, but as administration was twice daily the systemic dose was divided in two, 60,000 units being given at each injection.

The methods used can thus be summed up:

For the acutely inflamed stage, intramuscular injections of 15,000 units 3-hourly till localization occurs (120,000 units in 24 hours).

When fluctuation is detected, aspiration every 24 hours of all pus, and injection of penicillin solution up to two-thirds of the volume of the pus aspirated, providing this does not exceed 10 ml.

When localization is not complete and full retention of the injection can be ensured, intramuscular injections may be replaced by the injection of the full 24-hour dose of 120,000 units into the abscess cavity. When localization is complete, systemic treatment may be discontinued and, for reasons of economy, a solution whose concentration is 500 units per ml. can be used for injections.

When the abscesses contain more than 10 ml. of pus, incision, evacuation, suture, and twice-daily instillations of penicillin solutions following complete expression of pus. The choice of dose is

governed by the same considerations as apply to aspiration, but the systemic dose, as it is given twice daily, can be reduced to 60,000 units.

Where sinuses exist or are made, twice-daily expression and instillation by means of a rubber tube or wide-bore blunt-ended needle, the mouth of the sinus being occluded by a collodion dressing in the interval.

Finally, it should be emphasized that complete emptying of the cavity before each instillation is as essential a part of the treatment as it is in the more usual methods of open drainage.

Discussion

Little work on breast abscesses treated with penicillin has been reported up to date. Complaints in which the risk to life is small have naturally not attracted much attention in the last three years unless directly connected with the prosecution of the war. Yet the social consequences of this malady are considerable, and not least in this category must be placed the inability of mothers to continue suckling their babies when a virulent infection has arisen in the puerperium. Consequently a treatment which can obviate the routine use of stilboestrol has considerable advantages. Fraser (1944) described some not very satisfactory results from local treatment only, and O'Hanlon and MacClancy (1944) seem to have come to no definite conclusions as to the value of the local methods they employed. Hodgkinson and Nelson (1945) reported 24 cases of puerperal mastitis in which three-hourly intramuscular injections for five days appeared to have prevented the formation of breast abscesses in 24 cases, but they considered the use of stilboestrol necessary. Unfortunately no controls were observed simultaneously with this series, and the virulence of infection is known to vary from year to year. This seems to be borne out by our second survey (1945-6), in which no breast abscesses developed in either control or penicillin-treated series when treated early enough by chemotherapy, and the average healing time of the control abscesses was half that in the first survey.

The treatments described in the present paper are by no means unprecedented. One or other, or a combination, have been used in a variety of conditions such as acute suppurative mastoiditis (Florey and Florey, 1943; Macbeth, 1945; Johnson *et al.*, 1945), the suturing of wounds in battle casualties (War Office Report, 1943), acute pyogenic meningitis (Cairns *et al.*, 1944), empyema (Tillet *et al.*, 1944; Fatti *et al.*, 1946), pericarditis (Norman and Ainsworth, 1945), sinusitis (Hauser and Work, 1945), various abscess cavities (Florey and Williams, 1944; Barron and Mansfield, 1944; Noth and Hirschfeld, 1944), osteomyelitis of the mandible (Mowlem, 1944), and in chronic sinuses from osteomyelitis (Florey and Florey, 1943; Robertson, 1944). But the special problem attached to infection in the lactating breast is that of the facility with which multiple loculation occurs, so that the surgeon has been faced with the choice of doing the minimum of damage by incisions which may not drain all loculi completely, or of running the risk of spreading infection by breaking down dividing walls when exploring the extent of the suppuration. Unfortunately, as the controls show, sulphonamide therapy did not give complete protection against this spread, so it is satisfactory to find that it did not occur in any of the cases treated by systemic penicillin.

Now that economy in dosage is not a major consideration there is no reason to suppose that long-continued intramuscular penicillin combined with incision might not eliminate sepsis as satisfactorily as did the method used here of switching over to local administration as soon as it was practicable. The use of vehicles delaying absorption may also rob the intramuscular method of much of its discomfort by reducing injections to once or twice a day. The two great advantages of local treatment, however, are the ability to introduce such relatively enormous concentrations at the focus of infection that there is no need to regulate the dose according to the resistance of any particular staphylococcus and, possibly more important still, both local methods ensure drainage and irrigation of infected surfaces with the minimum of damage to tissues and, in consequence, a much increased rate of healing. In this connexion it must be recognized that the improved rate of healing is by no means due simply to the ability of penicillin to eliminate sepsis. It is, in the average case at least, equally due to

the fact that a technique can be adopted that enables healing to take place without the delay caused by the processes of granulation, contraction, and epithelization which the healing of an open wound necessitates.

The technique of finding and of fully aspirating small and sometimes deeply placed abscesses is a matter of skill which requires practice, and is not so easily acquired as that of incision, where anaesthesia enables the surgeon to conduct his exploration with greater ease. The danger in advocating this method of treatment appears to be that less importance is usually attributed to methods of treatment which do not need the panoply of an operating theatre for their execution. The inexperienced houseman or student is left to carry out aspirations without any preliminary instruction in technique or aseptic precautions (which should be as rigid at the bedside as in the theatre) the method of treatment will undoubtedly cause much suffering and unnecessary damage to surrounding breast tissue. Also, though the continued use of penicillin up to the last time a dressing was required undoubtedly reduced the risks of secondary infection (cf. infection of three controls with haemolytic streptococci), yet the clinical significance of an abscess cavity infected with organisms not susceptible to penicillin is not yet known. For this reason as much care as sepsis should be observed as should have been the rule before this chemotherapeutic agent was available.

Summary

In 1943-4 two simultaneous series of 18 patients suffering from breast abscesses were treated with present accepted methods and with a combination of intramuscular and local penicillin.

The average healing time in penicillin-treated cases was reduced to half that in controls.

Suppuration was hastened rather than retarded, but ceased more rapidly.

The use of stilboestrol was not necessary, and the mothers were able to continue suckling throughout treatment.

The number of operations was reduced from 22 to 4.

The total number of days during which treatment at the hospital was required was reduced from 661 to 232.

The methods of treatment with penicillin are described in text, and depend on the preliminary use of intramuscular injections followed by local administration.

ADDENDUM

A further controlled survey was carried out by two of us (M. A. M. B. and J. S. M.) in the winter and spring of 1945-6. The time penicillin or sulphathiazole was given systematically as a prophylactic measure to all inflamed breasts in the puerperium. Abscesses when they developed, were treated with similar methods to those described in this paper, but reliance was placed on incision and instillation in 50% of penicillin cases. These results will be published later, but they indicated that early prophylactic use of chemotherapy should reduce considerably the incidence of breast abscesses in the puerperium, and also that the less virulent the prevailing infection the less obvious the benefit accruing from the use of penicillin as compared with sulphathiazole.

These cases were observed and treated entirely at the Central Middlesex County Hospital at the suggestion of the Director, Dr. J. H. J. Jules, and owing to the kindness of Mr. T. G. I. James and Mr. J. D. Fergusson, in whose surgical wards some of the cases were nursed and whose responsibility they were. Mr. A. J. Wilson and Mr. H. Hashemian are thanked for their willing help on the surgical side; Dr. J. H. Humphrey and his staff for all the bacteriological examinations; the nursing staff for their enthusiasm and vigilance and Miss D. M. Barbour for the drawings.

CHEMOTHERAPY OF TUBERCULOSIS

RESEARCH DURING THE PAST 100 YEARS*

BY

P. D'ARCY HART, M.D., F.R.C.P.
Scientific Staff, Medical Research Council

1935-1946

PART II

The Sulphonamides and Sulphones

In 1932 Wells and Long suggested that the stimulus of some new success with other bacterial infections would be needed before the occurrence of any striking advance in the chemotherapy of tuberculosis. And in 1935, after 30 years of progress in the fields of protozoal and spirochaetal infection, but without the chemical mastery of any important general bacterial infection in humans, a substantial part of the bacterial front was broken. This, of course, was achieved by the successful use, in experimental streptococcal infection in mice, of azo-dyes containing a sulphonamide ($-SO_2NH_2$) group (Domagk). These were followed, first, by the dye-free sulphanilamide (*p*-aminobenzenesulphonamide, known since 1908), and then by numerous derivatives of the latter, known as the sulphonamides, and by various of the related sulphone ($-SO_2-$) compounds; and many of these synthetic drugs were introduced into medicine (Colebrook and others).

Encouraged by their reasonably high therapeutic index and their efficacy in acute infections, by their diffusibility, and by the presumption that their point of attack in the body was the parasites themselves, investigators tried a number of these sulpha drugs against tubercle bacilli in the test-tube and against experimental infection in animals, and a few of them in patients.

The first drug to be tested was the simplest—i.e., sulphanilamide (Rich and Follis, 1938; Follis and Rich, 1939); the net result of this and other inquiries was that in large and frequent doses some degree of inhibition of the disease in guinea-pigs could be obtained; but neither this compound, nor its derivatives sulphapyridine and sulphathiazole, nor others of the sulphonamide series, offered much hope of usefulness in the clinical sphere. A more promising field was opened up by the introduction, from 1939 onwards, of sulphone compounds into anti-tuberculosis chemotherapeutic experiments; the published data on these agents up to the end of 1944 have been admirably reviewed in detail by Tytler (1944-5), and only the

salient aspects of the present position will be mentioned here. The structure of the more important sulphone compounds and, for comparison, that of sulphanilamide is shown in Fig. 2 (modified from Tytler), and it will be seen that three have two phenyl rings linked by the sulphone (SO_2) group, while the fourth compound is somewhat different, having a phenyl and a thiazole group linked by the sulphone group.

The starting-point of the series, diaminodiphenylsulphone, showed some inhibitory effect in infected rabbits and guinea-pigs, but its low water-solubility and high toxicity were bars to its clinical application. The more complex "promin" (promanide) was easily soluble and had a low enough toxicity to warrant extended trials in experimental tuberculosis, which were given by Feldman and his colleagues at the Mayo Clinic and by other groups (see Tytler). The results showed this substance to be a striking inhibitor of the progress of the disease in guinea-pigs (the few observations made in mice—e.g., by Glover in 1945—were much less favourable). But when promin was tested in human pulmonary tuberculosis, although limited benefit was reported by some, the tolerance was found to be considerably lower than in the guinea-pig when the drug was given orally, unpleasant reactions—e.g., a (reversible) anaemia—occurring with some frequency; and while the toxic symptoms were much less evident after parenteral administration, so also was the clinical benefit (Zucker, Pinner, and Hyman, 1942; Heaf *et al.*, 1943; Hinshaw, Pfuetze, and Feldman, 1944; Dancey, Schmidt, and Wilkie, 1944). Experience with "diazone" in experimental tuberculosis in guinea-pigs resembled that with promin (see Tytler), but trials in human pulmonary disease produced conflicting reports, the majority of them unfavourable (Petter and Prenzlau, 1944; Benson and Goodman, 1945; Olson *et al.*, 1945; Pfuetze, 1945; Tice, Sweany, and Davison, 1946; Robitzek *et al.*, 1946). "Promizole" also gave encouraging results in experimental animals in the hands of Feldman, Hinshaw, and Mann (1944), who found it better tolerated by human beings than were the previously mentioned sulphone compounds. However, preliminary clinical trials of this compound in pulmonary tuberculosis have not indicated any marked superiority over promin (Hinshaw, Feldman, and Pfuetze, 1945); it is understood that a fully controlled clinical study is still in progress.

A fair summary of present experience with the sulphone compounds, as judged by those who have worked with them, is as follows. They exercise a deterrent effect on experimental tuberculosis, at least in some animal species, more than any previously tried chemotherapeutic agent; but, while early established lesions may regress and even be resolved, eradication of the virulent infection—a necessary criterion of cure in the acute or subacute disease of the hypersusceptible guinea-pig—is not attained. In man the small numbers and absence of simultaneous matched controls in most trials hitherto reported make assessment difficult, but the results appear nothing like as favourable as those in the guinea-pig; this is because a lower tolerance and risk of objectionable symptoms make adequate dosage difficult to achieve, or because the type of the disease is different, or possibly because the drugs may be altered in the body and become ineffective. At the best, some benefit in recent "exudative" lesions is attributable to these drugs, but there is not a consistent or unequivocal regression of the disease to quiescence or cure. Clinical use of those sulphones at present available seems likely to be limited to external or topical application,* to combination with other agents (e.g., streptomycin†), and to use in other mycobacterial infections (e.g., leprosy). "No definite place has been found for these drugs in treatment of the usual types of tuberculosis" (Hinshaw and Feldman, 1945a).‡

Other Organic Compounds

Besides the sulpha drugs, a large number of organic chemical compounds have during the past decade been reported to be inhibitory to growth of tubercle bacilli *in vitro*, and a few of

similarities. Some of them are purely synthetic artificially produced substances with no known counterpart in Nature; others are synthetic compounds related to some natural substance which has served as starting-point of the series; others are themselves of biological origin (these last are placed here rather than in Table III because they fall into convenient chemical groupings, whereas in Table III a provisional grouping by species of origin is adopted).

After the sulpha drugs, the most actively investigated compounds have been the chaulmoogra acids and structurally similar synthetic compounds, including synthetic cyclic and branched-chain, many-carboned fatty acids and their derivatives. Renewed interest in this group in tuberculosis springs partly from the historical favourable association of the chaulmoogra acids in the treatment of leprosy, and the earlier consequent research on tuberculosis with these and kindred synthetic

products. But work in this field has received new encouragement from the chemical analyses by Anderson and co-workers, extending over the past 20 years, of the lipids of the mycobacteria (see Anderson, 1943). These analyses stimulated the synthesis, by other workers, of lipid-soluble or lipophilic substances that might be expected to penetrate the supposed waxy or fatty "envelope" of the bacillus, or to injure it—e.g., through a surface tension effect. Furthermore, since Anderson's researches revealed the presence in the tubercle bacillus of a series of new branched-chain saturated fatty acids, one of which—phthioic acid—produced tubercle-like local lesions in the guinea-pig, the experiments with various synthetic branched-chain fatty acids made some years before (see above) took on new significance; and the synthesis of fatty acids of similar type to phthioic acid, and so chemically related to a natural bacillary constituent, seemed to offer reasonable promise of blocking some essential biosynthesis (Küster and Wagner-Jauregg, 1944; see also Polgar and Robinson, 1945). Thus there are at least two ideas on the mechanism of growth inhibition—one physico-chemical (fat lysis or penetration) and the other chemical (synthesis-blocking)—guiding current work on the tuberculostatic action of fatty acids and their derivatives. Unfortunately, tests against tuberculosis *in vivo* with selected *in vitro* active substances of this group have so far been little less disappointing than was the earlier work. Moreover, the hypothesis that antibacterial properties can be related to structural similarities with essential metabolites has still to be proved applicable to *M. tuberculosis* (see later). Finally, the results obtained with water-soluble sulphone compounds and with streptomycin, and the fact that the mycobacteria, despite their fatty structure, are more susceptible to water-soluble antiseptics than to fat-soluble compounds, emphasizes that the "lipophilic" approach to the chemotherapy of tuberculosis is not the only one, nor may it be the most fruitful (see discussions by Lehr and Bloch, 1945; Dubos, 1945, pp. 293-4).

The reasons for investigating the aromatic group of compounds, shown in Table II, are diverse. Benzophenone and allied compounds were tested because of their relationship to the sulphones. Naphthoquinone derivatives represent an attempt to interfere with the bacterial metabolism through a structural similarity to a hypothetical growth factor or growth stimulant of the vitamin K type. The use of iodobenzoic, iodoalicylic, and *p*-aminosalicylic acids arose from a search for growth inhibitors whose starting-point was the studies of Bernheim (1940, 1941) and others on the increase in oxygen uptake by washed suspensions of tubercle bacilli produced by benzoic and salicylic acids and certain other aromatic compounds; such studies suggested that these or chemically similar substances might play a part in the normal oxidations of the bacilli, and that substituted benzoates and salicylates might interfere with these oxidations and so inhibit growth. The recent renewed interest in dyes has its origin in the promise of the earlier work on tuberculosis by Lewis and others (see above); additional reasons for testing the acridine compounds (including aetbrin) are their clinical value in protozoal and bacterial infections, while indulin was used because it was wax-soluble.

In none of this list of compounds has there as yet been strong evidence of efficacy combined with safety in human pulmonary tuberculosis, though with some of them the clinical trials are not completed.* In one non-pulmonary condition, however, a substance has given highly encouraging results in the clinic. The substance is calciferol, whose benefit in lupus vulgaris, when used in high dosage, has been reported by Charpy in France and by Dowling and Thomas in this country, working independently. The results would seem striking and consistent enough to convince without simultaneous controls, and they appear to exceed those obtained in this disease with any previous internally administered remedy. It is to be hoped that further work will confirm and extend these observations, and provide an explanation, e.g., as to whether the calciferol is supplying a deficiency or is acting as a chemotherapeutic agent in the stricter sense. Moreover, while serious toxic reactions have

* A recent Swiss report (Junod, 1946) summarizes work in Japan with the alkaloid cepheranthine (from *Stephania cepherantha* of the family of Menispermaceae). It is active *in vitro* against tubercle bacilli, has low toxicity and is stated to produce arrest, reversal, and often resolution of the lesions of experimental tuberculosis. Improvement is claimed with minute doses in many types of clinical tuberculosis.

not so far been reported as accompanying this treatment, the possibility of calcium deposition in tissues will have to be watched.

An Antibiotic Age?

Soon after the impetus given to the search for chemotherapeutic agents in tuberculosis by the introduction of sulphonamide drugs in 1935, the bacterial front was further weakened and broken by the successful exploitation of antibiotic substances, none of which had hitherto found an undisputed place in medicine. In 1939 Dubos reported the extraction, from culture filtrates of a spore-forming soil bacillus, of the crude material tyrothricin, from which the crystalline polypeptides gramicidin and tyrocidin were derived; gramicidin was particularly interesting as being active *in vitro* and *in vivo* against certain Gram-positive bacterial species, but its toxicity restricted clinical use to topical application. In 1940—the almost-ideal chemotherapeutic properties of penicillin—extremely high efficacy in systemic infections by susceptible micro-organisms, little antagonistic action by body constituents, and virtual lack of toxicity—were demonstrated experimentally at the Oxford

School of Pathology. These two events stimulated widespread reactivation of this branch of microbiology, and antimicrobial agents were looked for in a multitude of living sources. In this search tuberculosis has figured prominently, particularly as penicillin was found not to inhibit the growth of tubercle bacilli in the test-tube or to retard significantly the development of the disease in experimental animals (Abraham *et al.*, 1941; Smith and Emmart, 1944).

In Table III are listed the majority of biological products recently reported as having tuberculostatic or tuberculocidal properties *in vitro*, under the headings of their microbial or other sources. It is already a formidable and rapidly growing collection; perhaps we are entering an antibiotic age in the chemotherapeutic investigation of tuberculosis. A notable feature of the list is the great preponderance of soil micro-organisms, showing the extent to which, in the past few years, soil and medical microbiology have become interconnected in a new way. It is evident also that there is particular concentration of interest around the genera *Aspergillus* and *Streptomyces*, and around the aerobic spore-bearing bacteria of the *B. subtilis* group. The range of activity of the antimicrobial substances produced by the various species listed extends in every instance beyond *M. tuberculosis*, though it is limited and selective; on the other hand, as with other antibiotics, the production tends to be species-specific or even strain-specific (as with streptomycin). In the great majority of the reports listed the *in vitro* evidence rests upon tests with culture fluids or crude concentrated extracts; in relatively few instances has a high degree of purification of the active substance yet been achieved. Names have, however, been conveniently created, even at an early stage of purification, to designate the active agent or agents. Some names—e.g., clotyocytine, streptomycin, subtilin, and licheniformin—indicate the genus or species of origin; others are based partly or wholly on the action of the antibiotic—e.g., mycoidin.

In only a few instances among these biological products is there information upon a full trial of efficacy in experimental tuberculous infection, either because investigations have not yet reached this stage, or because the active substance has proved too toxic or is inactivated *in vivo*, or for other reasons. Up to date I am aware of complete reports of such experiments for only two substances—streptothricin and streptomycin.* Since the former showed undesirable toxic effects in laboratory animals and failed, in the dosage practicable, to control experimental tuberculosis in the guinea-pig (Feldman and Hinshaw, 1945a), it has dropped into the background.

Streptomycin

Streptomycin was discovered in 1944 by Waksman, one of the world's leading authorities on the actinomycetes family, and his colleagues (Schatz, Bugie, and Waksman, 1944; for a review see Waksman and Schatz, 1945). This was the result of a purposeful search among soil micro-organisms for antibiotic agents active against the Gram-negative bacteria and the (Gram-positive) mycobacteria, and suitable for clinical application. The name streptomycin is "derived from the generic designation given to the sporulating and aerial-mycelium-producing group of actinomycetes—namely, *Streptomyces*" (Waksman and Schatz, 1945). The antibiotic was originally found in one particular strain of *Streptomyces griseus*, and, indeed, production has been noted in only a few of the other strains of this species since examined. Streptomycin has been obtained apparently pure. The low toxicity of the purified product for experimental animals (e.g., Molitor *et al.*, 1946; Molitor, 1946), its high power of inhibiting growth *in vitro* of *M. tuberculosis* (Schatz and Waksman, 1944; Emmart, 1945; Youmans, 1945; Youmans and Feldman, 1946), and its survival when introduced into the body, led to extensive tests in experimental tuberculous infection in guinea-pigs (Feldman and Hinshaw, 1944; Feldman, Hinshaw, and Mann, 1945; Smith and McClosky, 1945a) and in mice (Youmans and McCarter, 1945). In guinea-pigs the results of treatment begun simultaneously with, or some weeks after, infection were strikingly better than those with any previous chemotherapeutic agent, and the

TABLE III.—Substances from Natural Sources Inhibitory *in vitro* to Growth of *M. tuberculosis*, grouped according to Species of Origin (Recent Publications)

Species	Name of Agent	References
(a) Fungi:		
<i>A. fumigatus</i> ..	Fumigacin*	Waksman, Horning, and Spencer (1942); Schatz and Waksman (1944)
<i>A. fumigatus</i> ..	Helvolic acid*	Chain <i>et al.</i> (1943); Jennings (1945)
<i>A. fumigatus</i> ..	Aspergillin	Soltys (1944, 1946)
<i>A. fumigatus</i> ..	(Unnamed)	Asbeskov and Strelitz (1945)
<i>A. flavus</i> ..	Aspergilline acid	Goth (1945)
<i>A. flavus</i> ..	(Unnamed) ₂	Bush <i>et al.</i> (1945)
<i>A. clavatus</i> ..	Clavacin†	Waksman, Horning, and Spencer (1942); Schatz and Waksman (1944)
<i>A. ustus</i> ..	Ustin	Kurine (1945); Hoserboom and Craig (1946); Doering <i>et al.</i> (1946)
<i>A. albus</i> , <i>niger</i> , etc. ..	(Unnamed)	Zorzi (1940)
<i>A. (unnamed)</i> ..	Mycoidin	Gerber and Gross (1945, 1946)
<i>A. (unnamed)</i> ..	(Unnamed)	Kallos (1945)
<i>P. (unnamed)</i> ..	(Unnamed)	Miller and Reckate (1944)
<i>F. javanicum</i> ..	Javanicin	Arinstein, Cook, and Lacey (1946)
<i>Ch. cochlioides</i> ..	Chaetomin	Schatz and Waksman (1944); Waksman and Bugie (1944); Geiger, Conn, and Waksman (1944)
(b) Actinomycetes:		
<i>S. griseus</i> ..	Streptomycin	Schatz and Waksman (1944); Schatz, Bugie, and Waksman (1944)
<i>S. lavandulae</i> ..	Streptothricin	Schatz and Waksman (1944); Waksman and Woodruff (1942); Woodruff and Foster (1944)
<i>S. antibioticus</i> ..	Actinomycin	Schatz and Waksman (1944); Waksman and Woodruff (1944); Waksman and Tishler (1942)
<i>Pr. gardneri</i> ..	Proactinomycin	Floney, Jennings, and Sanders (1945)
<i>Pr. cyaneus</i> ..	Litmocidin	Gause (1946); Brazhnikova (1946)
(c) Aerobic spore-forming bacteria:		
<i>B. subtilis</i> ..	Subtilina	Fontes Magarao <i>et al.</i> (1944)
<i>B. subtilis</i> ..	Subtilin	Jansen and Hirschmann (1944); Salle and Jann (1945)
<i>B. subtilis</i> ..	Bacillin	Foster and Woodruff (1946)
<i>B. subtilis</i> ..	Eumycin	Johnson and Burdon (1946)
<i>B. licheniformis</i> ..	Licheniformin	Callow and Hart (1946)
(d) Non-sporing bacteria:		
<i>B. larvae</i> ..	(Unnamed)	Holst (1945)
Milk streptococcus ..	(Unnamed)	Mattick and Hirsch (1944, 1945); Mattick (1946); cf. Oxford (1944)
(e) Higher plants:		
<i>Allium sativum</i> (garlic)	(Unnamed)	Courmont <i>et al.</i> (1937) Rao <i>et al.</i> (1946)
Onion and garlic ..	Phytonicides	See Tokin (1945)
<i>Clitocybe gigantea</i> ..	Clitocybine	Hollande (1945)
(fairly-ring mushroom)		
<i>Plumbago europea</i> ..	Plumbagol	Saint Rat, Olivier, and Chouteau (1946)
Chlorophyll derivatives and related compounds	(Unnamed)	Daly, Heller, and Schneider (1939)
<i>Buellia canescens</i> (lichen)	Diploicin	Barry (1946)

* Helvolic acid is related to, or identical with, fumigacin.

† Clavacin is identical with clavatin from the same species, claviformin from *P. claviforme*, and patulin from *P. patulinum*.

A. = *Aspergillus*. P. = *Penicillium*. F. = *Fusarium*. Ch. = *Chaetomium*. S. = *Streptomyces*. Pr. = *Proactinomycetes*. B. = *Bacillus*.

* A recent note by Salle and Jann (1946) states that subtilin produces "a definite suppressive effect on the course of experimental tuberculosis in guinea-pigs."

substance was well tolerated. Not only was the development of the disease noticeably inhibited, but arrest and even eradication of established lesions were noted. In mice the effect was not quite so striking, possibly because of a different balance between the doses of drug and infection; definite suppression of the disease process was, however, evident. Owing to shortage of supplies, systematic clinical trials of streptomycin in tuberculosis have so far been mainly confined to its country of origin—the United States—under the supervision of the National Research Council (see Keefer, 1946), and the few published reports are of a preliminary nature (Hinshaw and Feldman, 1945b, 1946—54 miscellaneous cases with limited improvement in some; Cooke *et al.*, 1946—case of tuberculous meningitis with apparent recovery; Figi, Hinshaw, and Feldman, 1946—case of laryngeal tuberculosis with striking improvement; Cook *et al.*, 1946—12 cases of genito-urinary tuberculosis with improvement in some; Baggenstoss, Feldman, and Hinshaw, 1946—histopathology of regressing human lesions).

As seen from this side of the Atlantic, one might summarize the present status of streptomycin in tuberculosis as follows. This antibiotic seems more promising than any previous chemotherapeutic agent. In animals its toxicity is less than, and its effect on experimental infection better than, the best of the sulphone compounds. In man prolonged administration appears to have been free of serious and uncontrollable toxic reactions, though, as in animals, histamine-like responses, evidence of (reversible) renal "irritation," eighth-nerve symptoms, neuritis, and dermatitis have been reported; it seems possible that some of these reactions are due to impurities in certain of the preparations used. The effect on human tuberculosis justifies cautious optimism for certain forms of the disease, but, subject to any very recent information, Waksman's own words of November, 1945, still hold: "Prolonged treatment and studies of many cases are absolute prerequisites for any serious consideration of the efficacy of streptomycin in the treatment of tuberculosis. To date sufficient information has not yet been accumulated" (Waksman and Schatz, 1945). The need for caution has been learned from bitter experience of the past failures with gold, copper, and tuberculin, and from the false promise given by animal experiments with the sulphones. Should streptomycin occupy no more than a temporary place in tuberculosis therapy, the resulting increase in biological and chemical knowledge will nevertheless be very considerable and will assist in further advances.* †

Streptomycin has certain apparently unsatisfactory properties. Like penicillin, it is poorly absorbed from the alimentary canal, so that administration has to be parenteral. Unlike penicillin, it is a base and its activity *in vitro* is reduced by a lowered pH, which it might encounter in pus; how far this objection is of practical importance is not decided. A much greater possible disadvantage is that drug resistance is rather easily acquired by the tubercle bacillus and other susceptible micro-organisms, both *in vitro* and *in vivo* (Youmans and Feldman, 1946; Youmans *et al.*, 1946), and this is particularly liable to occur during a prolonged course of treatment. This is one reason why other chemotherapeutic agents would be desirable for use in tuberculosis, even should streptomycin justify present hopes.

Outlook for the Future

The purpose of this historical review would not be served unless it helped in the assessment of the present position and future prospects. It is therefore relevant to consider some of the difficulties in the path of those who are searching for chemotherapeutic agents in tuberculosis.

In common with all chemical attack on systemic infective disease, the prime consideration is that the chemotherapeutic

index of an agent must be reasonably high—i.e., that its effective dose must be substantially lower than the dose toxic to the host. This is where the great majority of prospective agents that are tuberculostatic in the test-tube fall down when tested in the infected body. Other general reasons are failure to disseminate so as to reach the infection site, inactivation by antagonistic substances in the blood or other body constituents, and excessive speed of destruction or excretion; while acquired resistance to the agent by the bacterial parasite is particularly liable to occur when, as in tuberculosis, prolonged administration is required. One general chemotherapeutic aim, however, may have to be modified in the case of human tuberculosis—namely, complete internal disinfection; in fact, when we consider the benign and possibly protective infection which so many of us harbour, the latter may not be necessarily even an essential objective.

There are also difficulties more peculiar to tuberculosis. To be directly inhibitory or lethal to this micro-organism an agent must penetrate the relatively avascular tubercle, enter the possibly vulnerable phagocyte that may enclose the bacillus, and penetrate the "hardy wax-armoured bacillus" itself (Wells and Long, 1932, p. 391); dense fibrotic encapsulation may also constitute a barrier. These difficulties led some workers to see more hope in the indirect attack—by chemical stimulation of the tissue cells around the tubercles, or of the host's defensive mechanisms generally, without contact with the bacilli, as is believed to be the mode of action of heavy metals, certain dyes, etc. Some of these obstacles have, however, probably been overrated. Thus Rich (1945) states: "The tubercle, in spite of its compact, solid appearance, must be permeable to substances in solution, else neither the cells nor the enclosed bacilli could receive the nutritive material necessary for their survival." Actually many diffusible foreign substances will pass from the blood stream into the centres of tubercles and caseous areas—e.g., various vital dyes, iodides, and iron—and some become concentrated therein: penetration of colloidal substances is, of course, much less likely, unless the molecules be small. Rich concludes that many chemotherapeutic substances can reach bacilli in epithelioid cells or in caseous lesions, but that when enclosed in living mononuclear phagocytes the agent must be capable of surviving the internal environment of such cells. If the agent reaches the bacillus, even the reputed waxy or fatty barrier, often supposed to be responsible for the remarkably low susceptibility of mycobacteria to many ordinary chemical antiseptics, seems doubtful in the light of the growth-inhibitory effect, both *in vivo* and *in vitro*, of water-soluble substances such as certain sulphones and streptomycin. Moreover, whether the abundance and variety of the lipids does or does not confer resistance, there is at present no proof that these lipids are organized as a cell capsule or envelope (see Dubos, 1945).

Special difficulties of a technical character also slow the rate of advance. On the biological side, *in vitro* tests are more time-consuming with *M. tuberculosis* than with many bacteria, since the organism grows slowly and uniform inocula and other conditions are not easily attained; recent improvements in media, in the use of submerged culture, etc., may assist (e.g., see Dubos and Davis, 1946). Animal tests also are prolonged, and they need larger amounts of the test substance than do tests in many other infections. The lesions produced in the commonly used experimental animals tend to be acute or subacute, and may differ in other respects from the chronic fibrocaceous lesions of reinfection comprising a large part of adult tuberculosis in man; and, although reinfection can be readily produced in animals, the difficulties of providing a uniform series for chemotherapeutic trials are increased. As to species of animal, the guinea-pig has been the animal of choice for most workers (Feldman and Hinshaw, 1945b), but owing to its lack of natural resistance and comparatively large drug requirements some have turned to the mouse, in spite of its rather atypical non-neurotic lesions (e.g., Glover, 1945; Youmans and McCarter, 1945; Martin, 1946). The chorio-allantoic membrane of the chick embryo is also used, but the tests are not yet on a very firm foundation and some of the techniques are open to criticism. Feldman and Hinshaw (1945b) have made excellent suggestions for standard procedures for chemotherapeutic tests in experimental tuberculosis, with special reference to guinea-pigs. Their criteria for a successful agent are

* For a recent evaluation of the efficacy of streptomycin in experimental tuberculosis, see Feldman (1946).

† A report of 1,000 patients with various infections, treated by streptomycin in the United States, has just appeared (National Research Council, 1946); 87 cases of tuberculosis of the more advanced types are included. Guidance on dosage and administration is given (see also Hinshaw and Herrell, 1946) and toxic manifestations detailed. It is concluded tentatively that streptomycin has a suppressive, though not usually eradivative, action in military, laryngeal, meningitic, skin, and renal tuberculosis, and in exudative pulmonary tuberculosis: there is still doubt as to the sequel after discontinuance of treatment. The side-reactions appear more common and somewhat more significant than earlier reports suggest, and certain of them are noted even with apparently pure preparations.

(abbreviated): (1) satisfactory tolerance and absence of serious or irreversible physiological derangements; (2) reversal of established progressive disease to non-progressiveness, resolution, fibrosis, or calcification; (3) eradication of virulent infection; (4) results to be achieved in a reasonable period. In such tests it would be desirable to use "strains of tubercle bacilli whose origin, type, and virulence are known and can, within limits, be guaranteed" (National Tuberculosis Association, 1946).

The preparation of synthetic substances and antibiotic material for *in vivo* trials against experimental tuberculosis requires much initial labour, making *in vitro* "screening" almost a necessity—even though the great majority of agents thus selected as worthy of further attention must be expected to prove ineffective therapeutically. Possibly some more significant screening tests than those that measure growth inhibition will be devised; present alternatives, such as observations on the effect of drugs on oxygen uptake of the bacilli in the resting state (e.g., Bernheim, 1941; Franke and Schillinger, 1944), are of doubtful value in this connexion. Prognostication of the effect in human beings from behaviour of chemotherapeutic agents in experimental tuberculosis provides further misleading possibilities. A good example of lack of correlation between results in test-tube, experimental animal, and man is given by the individual sulphonamides, the best of which are not highly active *in vitro* but give very encouraging results in guinea-pigs, yet have been disappointing clinically. However, few would oppose the principle that new agents of significant toxicity should be administered in human tuberculosis only after promising animal trials. This, of course, does not mean that efficacious agents may not still be first discovered at the clinic or the bedside—such success is shown strikingly in the recent treatment of lupus vulgaris with vitamin D.

The difficulties of evaluating chemotherapeutic trials in man are far greater than in experimental animals. Selection of cases provides a dilemma, for while improvement is most to be expected in early "exudative" lesions unaccompanied by much destruction or fibrosis (as revealed increasingly by mass radiography), these are just the cases that may improve with rest alone or no treatment at all; on the other hand, in chronic fibrocavitary disease the prospect of improvement is doubtful and, if it occurs, may be confused with naturally occurring spontaneous regression. Such considerations call for simultaneous matched controls, an adequate duration of the trial, and an intelligent use of statistics; however, owing to the very obvious obstacles in selecting controls and in giving them inert preparations for some months, most trials have relied instead upon the pre-chemotherapeutic behaviour of the treated patients and on the general clinical experience of the medical observers. Patients and controls should, so far as is possible, form homogeneous groups susceptible of classification, with emphasis in the first instance on bronchopneumonic, "labile," reversible changes. The foregoing difficulties and others inherent in clinical trials, as well as standard procedures to overcome them, are discussed by Hinshaw and Feldman (1944). There is divergence of opinion among experienced workers on some of the points; thus, Zucker, Pinner, and Hyman (1942) and Pinner (1944) hold that, with proper selection of material, preliminary results are obtainable in a brief period, and any positive effect should be obvious enough without controls. Now, if any type of case is suitable for non-controlled observation, it is the "acute" rapidly developing forms of pulmonary disease seen in young adults, and meningeal and some other non-pulmonary forms. One might therefore ask: Will a chemotherapeutic agent produce dramatic enough reversal of progression in such a case to prove that the agent was the determining factor, as has been achieved with penicillin in the absence of direct controls? It is a great deal to ask of it. Or will the ambiguities of "sanocrysin" be repeated? The current clinical trials of streptomycin are relevant to this question, and it should be noted that success has been reported in a few cases of tuberculous meningitis.

Conclusion

Having thus discussed the history of, and some of the research problems particularly involved in, the search for chemotherapeutic agents in tuberculosis, we can see that two paths are being followed: by way of substances synthesized biologically by various forms of plant life, and by way of

products synthesized in the laboratory by the chemist. Along the first path, as with the initial discovery of penicillin, little chemical principle is at present involved in the exploratory phases, which are therefore somewhat empirical. Along the second path the design of synthetic agents is being based on a number of suggestive "leads"; but one fundamental guide is as yet little developed. This is the hypothesis that many antibacterial agents function in virtue of structural similarities to substances that participate in the essential metabolic processes of the bacterial cells ("essential metabolites"), such chemical similarities leading to interference with these processes and so to inhibition of growth. This concept was much strengthened by the study in 1940 of the mutual antagonism between sulphanilamide and the closely related *p*-aminobenzoic acid in the inhibition of streptococci; and it has been used since as a basis for the design of fresh synthetic growth inhibitors for a variety of micro-organisms in which essential metabolites could be defined (e.g., see Knight, 1946). Knowledge of the metabolism of *M. tuberculosis* is, however, still very deficient, this micro-organism seeming able to use the simplest nutrients, to dispense with preformed growth factors, and to synthesize all its essential metabolites—at least after adaptation to the *in vitro* cultural environment in which it is usually studied. Efforts to define its essential metabolites, and to model growth inhibitors on their structure, have so far been confined to lipids, without as yet much result (see above); but further study of the nutritional requirements and metabolic reactions of this micro-organism as a whole may provide a valuable guide to the synthetic design of anti-metabolites that will block some biosynthesis essential to the functioning of its cells.

These two paths along which present work is moving, which originated separately about 50 years ago, can be expected to converge and ultimately to meet; for knowledge of the chemical structure of antibiotic substances may promote laboratory synthesis of active related compounds, while knowledge of the point of interference of such substances may give new information on the essential metabolism of the tubercle bacillus and lead to the purposeful creation of simpler synthetic anti-metabolites.

Should a real measure of success be reached with one or a number of chemotherapeutic agents this is not likely by itself to lead to the eradication of tuberculosis. During the past decade much else has been added to the understanding of this disease and to the ability to control it. Fuller appreciation of the importance of social factors in its incidence and spread, and of the value of social assistance (both financial and re-abling) in consolidating treatment; greater emphasis on the factor of household contact and on earlier diagnosis by means of mass radiography; and the coming to maturity of the various methods of collapse therapy and other surgical procedures: these are among the features of this period in the more favourably placed countries, such as Britain. It is improbable that success in chemotherapy will supersede all the tried and trusted methods of control acquired through the years which are applied to the individual patient, to his family, and to the community. Thus, rest can be expected to remain the foundation of treatment, and surgical methods to be needed in certain types of case; the conditions of life to which the patient returns will surely affect critically the ultimate results of even the most spectacular chemotherapy; and the state of housing and nutrition of the people generally may be expected to continue to influence the secular trend of tuberculosis mortality and incidence. There are in the world perhaps between 10 and 20 million sufferers from active tuberculosis. In order to reduce this inroad on world health we shall probably need most of the reasonable measures—social and economic, preventive and therapeutic—that we possess now or that we can acquire in the future. The attack will remain multiple; the tactics will change.

AMBIGUOUS INHIBITION OF STAPHYLOCOCCI BY PENICILLIN INACTIVATED WITH PENICILLINASE

BY

R. F. HUNWICKE, B.Sc., F.R.I.C.

in the Bacteriological Department, Glaxo Laboratories, Ltd., Greenford)

some time past penicillinase prepared by the growth of strain of *B. subtilis* in broth has been used in this laboratory to inactivate penicillin before testing for sterility. A batch of penicillinase is assayed by a method devised in Bacteriological Laboratory of Messrs. Boots Pure Drug Co., (personal communication).

1:20 dilution of the penicillinase preparation in water is added in ascending quantities to a series of broth tubes each containing 4,000 units of penicillin. These are inoculated with a loopful of a broth culture of a sensitive staphylococcus. The end-point is read after 40 hours' incubation at 37° C. On one occasion 20,000 units of penicillin was erroneously added to each tube in setting up the assay. On this being realized the penicillinase was diluted 1:4 instead of 1:20, the assumption being that this would give the same result, since the portion of penicillinase to penicillin in each tube would be the same. However, no growth of staphylococcus occurred in any of the tubes. The assay was then repeated at the normal 1 of dilution and an end-point was obtained as usual near middle of the range.

This incident suggested that the ability of staphylococci to grow in broth plus inactivated penicillin is limited to a certain degree of concentration of penicillin.

Experimental Results

It was first shown that failure to grow was not due to a change in pH of the broth. The following experiment was then tried out. Serial dilutions of penicillin in broth were made in metrical progression, beginning with 200,000 units, the last containing 781 units. Corresponding dilutions of penicillinase in water were made and 1 ml. of each dilution was added to each corresponding tube of penicillin, so that the proportion of penicillinase to penicillin was the same in each tube. A loopful of staphylococcus broth culture was added to each tube and the series was incubated at 37° C. The tubes were examined first after 24 hours' incubation; growth had occurred in the tube containing 6,250 units of penicillin. Examination after 40 hours showed growth in the tubes containing 500, 3,125, and 1,562 units, but no growth at the four highest dilutions or at the lowest one.

The experiment was then repeated using quantities of penicillin from 100,000 down to 390 units, and on this occasion examination of the tubes was made at hourly intervals. Growth occurred with 6,250 units at less than 19 hours (as it did in a control tube of plain broth), with 12,500 units in 22 hours, with 3,125 units in 24 hours, and with 1,562 units in 30 hours. No growth occurred with 100,000, 50,000, 25,000, 781, or 390 units up to 3 days.

The results of three further experiments are given in Table I.

TABLE I

Penicillin (Units)	Expt. 1	Expt. 2	Expt. 3
100,000	0	0	~
50,000	0	0	0
25,000	0	0	0
12,500	0	± 3 days	(4) + 3 days
6,250	(2) + 22 hours	(3) + 26 hours	(1) + 24 hours
3,125	(1) + 21 "	(2) + 24 "	(2) + 23 "
1,562	(3) + 23 "	(1) + 22 "	(3) + 40 "
781	(4) + 30 "	(4) + 27 "	0
390	0	(5) + 40 "	0
195	—	± 3 days	0

Control + 18 hours

0 = No growth. + = Normal growth. ± = Trace of growth. — = Not done.

It will be seen that growth always begins first in one of the tubes near the middle of the series and spreads outwards through the tubes on either side of the first, though the order is not constant. If the solutions in the high-concentration tubes in which no growth has occurred are diluted with broth to fall within the range of the positive tubes, growth immediately occurs, sometimes being visible in as short a time as three hours after dilution, showing that the penicillin has in fact been inactivated and that the staphylococci have not been killed by the high concentration, for only the original inoculum is still present. Similar results were obtained in other experiments, using three different samples of penicillinase prepared in media other than papain digest broth.

The penicillin used in all the foregoing experiments was manufactured some time ago and was relatively impure, containing 700 to 800 units per mg., assayed against staphylococcus.

Inhibition of growth is not due to anything in the penicillinase; this was shown by making serial dilutions of penicillinase in broth of the same strengths as used in the experiments with penicillin and inoculating with the same staphylococcus. Growth occurred in 18 hours in every tube. It seems evident, therefore, that there is some substance present with the penicillin which, while not affected by penicillinase, in high concentration inhibits the growth of staphylococci.

Confirmation of this hypothesis was obtained by repeating the experiment using purified penicillin, containing 1,600 units per mg., assayed against staphylococcus. An amount of this material containing 100,000 units was diluted serially and each tube was treated with the corresponding quantity of the penicillinase used in previous experiments. The tubes were inoculated from a broth culture of the same staphylococcus. Growth occurred simultaneously in 18 hours with the six highest concentrations, from 100,000 units down to and including 6,250 units. It occurred with 3,125 units in 21 hours, with 1,562 and 781 units in 40 hours, and with 390 units in 3 days. No growth occurred with 195 units up to 5 days. Inhibition at the low end of the scale thus occurs even with pure penicillin.

Three further experiments were done with penicillin from batches having potencies of 1,000, 1,210, and 1,450 units per mg respectively. The results were as shown in Table II.

TABLE II

Penicillin (Units)	1,000 u./mg.	1,210 u./mg.	1,450 u./mg.
100,000	(7) ± 3 days	(5) ± 3 days	(5) ± 42 hours
50,000	(3) + 20 hours	(1) { ± 18 hours }	(1) + 20 "
25,000	(2) + 18 "	(3) + 24 "	(3) + 24 "
12,500	(1) + 16 "	(2) + 20 hours	(2) + 24 "
6,250	(4) + 22 "	(3) + 24 "	(4) + 40 "
3,125	(5) + 40 "	(4) + 40 "	(6) + 3 days
1,562	(6) ± 3 days	0	0
781	0	0	0
390	0	0	0
195	0	0	0

Control + 16 hours

It will be seen that, as the potency of the penicillin in units per mg. increases, the first tube to show growth is one step higher in the series. As has been shown, when a potency of 1,600 units per mg. is reached the phenomenon no longer occurs, growth occurring simultaneously with all the higher concentrations.

Further evidence that inhibition with high concentrations of penicillin is due to impurities was obtained by inactivating in the autoclave, a solution of penicillin containing 100,000 units in 5 ml., or 20,000 units per ml., and inoculating with one loopful of staphylococcus broth culture. No growth occurred in 7 days, though it occurred in lower concentrations.

Speculation about the nature of any unknown inhibitory substances and their possible therapeutic action is beyond the scope of this paper.

Failure of growth at the very low concentrations of penicillin must be a phenomenon quite distinct from that observed at the other end of the scale and is much more difficult to interpret. In an attempt to elucidate it the following experiment was done:

To four tubes of broth each containing 195 units of penicillin were added the corresponding concentration of penicillinase and one loopful of staphylococcus broth culture. They were incubated for three days; no growth occurred. They were then treated as follows:

Tube 1: excess penicillinase added. Tube 2: one loopful of staphylococcus broth culture added. Tube 3: excess penicillinase and one loopful of staphylococcus broth culture added. Tube 4: no additions. All were incubated at 37° C. with a broth control.

The results were:—Tube 1: +, 24 hours; tube 2: +, 4 hours; tube 3: +, 4 hours; tube 4: 0, 7 days. Control: +, 24 hours.

Tube 1 shows that the original inoculum was still living, but that the original amount of penicillinase added was not sufficient to inactivate the penicillin. Tube 2 indicated that the penicillin had been sufficiently reduced in activity to allow a fresh inoculum to grow; tube 3 is thus redundant, in view of the results with tubes 1 and 2. Tube 4 confirms that the penicillin had not been inactivated by the original addition of penicillinase. The extremely rapid growth in tubes 2 and 3—full growth with maximum turbidity in 4 hours—is difficult to explain. It seems to be analogous to the very rapid growth, noted above, with high concentrations diluted to fall within the critical range of concentration. Both these observations seem to indicate that treatment of penicillin with penicillinase at sub-maximal levels for several days increases the susceptibility of the medium to growth of staphylococcus when the conditions are altered sufficiently to allow growth to take place. That the alteration is in the medium and not in the inoculum seems clear from tubes 2 and 3, where the inoculum was fresh.

Discussion

The observations here reported are, apart from any academic interest, of practical importance for sterility-testing of penicillin.

This laboratory is frequently called upon to test for sterility dried penicillin in phials containing up to 1,000,000 units. In the light of the observation here reported it is clear that to make certain of getting growth of sensitive contaminants the final dilution in the test medium should be related to the potency of the sample in units per mg. With potencies of less than 1,000 units per mg. it should be of the order of 1:100. However, with penicillin of recent manufacture, potencies of at least 1,400 units per mg. are usual, and it should not be necessary with such samples to employ volumes of test broth larger than those normally used for sterility testing. Where very low concentrations of penicillin are to be tested for sterility care must be taken to add gross excess of penicillinase, of the order of 10 times the equivalent quantity, whatever the potency of the sample. This does not normally arise in practice.

Apart from the above practical considerations, the phenomenon described is interesting from several points of view. Inhibition by high concentrations suggests that impurities in penicillin exert on staphylococci an inhibitory effect that is not a true penicillin effect, for it does not occur with "pure" penicillin. Inhibition at the low end of the scale is more difficult to understand. It would seem that penicillinase does not act proportionately to its concentration—that the relationship of penicillinase activity to concentration of penicillin is in fact

not linear. Consequently the value obtained by the method assay described holds good only for a limited range of penicillin unitage—round about 4,000 units. The quantitative relationship of penicillinase and penicillin may have a bearing on the generally assumed enzymic action of penicillinase.

The extremely rapid growth of staphylococci (full growth from a single loopful in 3 to 4 hours at 37° C.) after reduction to a normal dilution a concentrated penicillin solution in which growth has so far failed to occur is a most striking phenomenon and difficult to explain. So also is the similar rapid growth of very dilute penicillin in broth after excess penicillinase has been added to a tube in which no growth has so far occurred. Such rapid growth has never previously been observed in the laboratory: it would seem to merit further study.

Summary

Staphylococci are inhibited by penicillin above a certain concentration, notwithstanding that the penicillin is shown to have been inactivated by penicillinase.

This does not occur with "pure" penicillin, suggesting that inhibition is due to impurities.

Similar inhibition occurs in penicillin dilutions in broth below certain concentration. In this instance the inhibition is due to penicillinase having failed to inactivate.

In both instances, if the penicillin in broth is rendered capable of supporting growth by diluting the high concentrations or by adding excess penicillinase to low concentrations, growth of staphylococci occurs with extraordinary rapidity.

The implications of the observations are discussed from the point of view of sterility-testing of penicillin.

MESENTERIC OCCLUSION

A REVIEW OF RECENT METHODS OF TREATMENT WITH NOTES ON SIX INSTANCES

BY

H. MORGAN WILLIAMS, M.B., B.S., F.R.C.S.

Mesenteric occlusion is one of the rarer abdominal disasters and one that is very difficult to diagnose pre-operatively, very difficult to treat, and recovery from which is most exceptional. Having had experience of six cases in the last four years, with three recoveries, my interest was aroused and I was stimulated to consult the literature.

The occlusion may be arterial or venous, and may be thrombotic or embolic. Venous thrombosis is usually a complication of a septic process within the peritoneum. Arterial embolism may arise from cardiac vegetations, whereas arterial thrombosis is likely in blood disorders—e.g., purpura. The arterial architecture is very important. The small intestine is supplied entirely from branches of the superior mesenteric artery dividing into a series of arcades. There is no marginal artery such as is found in the large intestine. When an occlusion occurs in the area of the small intestine it has been suggested by Litten (1875) that a violent spastic contraction occurs from the ligament of Treitz to the middle of the transverse colon. The last case described below is difficult to explain on an arterio-anatomical basis. The symptoms may be acute or subacute: constant pain is a regular feature, with only moderate or ill-defined tenderness. Vomiting is more likely if the upper reaches of the alimentary tract are involved. Constipation or diarrhoea may occur.

Diagnosis may be facilitated in subacute cases by a plain skiagram, where gas is seen as far as the splenic flexure as a barium enema reveals no obstruction. Prognosis is always grave, but patients have lived many years after operation.

Treatment must be decided after the state of affairs has been assessed at laparotomy. The appearances found vary considerably: the bowel affected may be black, and profuse haemorrhagic exudate may be present; in others a deeper cyanotic colour is seen, with ecchymoses and less heavily blood-stained exudate. If the affected length of bowel is not too great and the patient's condition is good enough, a resection can be undertaken and anastomosis performed. Ficarra (1944) describes fifteen cases, three of which were cured by resection; Atkin (1937) reports recovery by resection, exteriorization, and subse-

ant closure; D'Abreu and Humble (1946) describe cases where small intestine was removed successfully, and careful administration of heparin subsequently is emphasized as an important factor. In all cases of cure resection had been performed, except in a case of lymphatic leukaemia (Murray and Lissimore, 1944), where the only treatment was dicourol 0.05 g. on alternate days. In three of the cases quoted below it will be seen that recovery occurred without resection; only one case was heparin used. The routine followed (after missing the possibility or advisability of resection) was to institute an intravenous glucose-saline drip and, when vomiting threatened, to aspirate the gastric contents through a Ryle's tube. Except in one slight case (No. 4) this was maintained for 7 days, and then the bowels were opened by pituitrin 0.5 ml. and a turpentine enema.

Case Histories

Case 1.—Miss C., aged 80. The patient was an arteriosclerotic subject with some evidence of myocardial failure. She had diffuse abdominal pain for two days, constipation, and vomiting; and there was distension without localized tenderness. Laparotomy showed anosis and distension of almost the whole of the small intestine. Nothing could be done, and the abdomen was closed. The patient died a few hours later.

Case 2.—Captain P., aged 76, a stout man retired from seafaring, had two days' abdominal pain—not localized; vomiting; and constipation. A few days before this he had developed a slight purpura. Examination showed a dry tongue and distended abdomen, with no localizing features; his general condition was good. The diagnosis was mesenteric occlusion. Laparotomy brought to light mesenteric occlusion affecting about five feet (1.5 m.) of small intestine. Resection was immediately decided upon and rapidly performed with an end-to-end anastomosis. The patient's condition on return to bed was good; but he never recovered consciousness, dying twenty-four hours later. Evidence suggested death from cerebral thrombosis.

Case 3.—Mrs. C., aged 58, had two days' history of right-sided abdominal pain with profuse diarrhoea; temperature 99° F. (7.2° C.), pulse 92. Her previous health had been good. Examination showed a dry tongue, and the abdomen slightly distended, with marked tenderness in the right iliac fossa. The diagnosis was appendicitis. Operation revealed a normal appendix, but the bowel was cyanosed from a point just distal to the caecum to the upper part of the descending colon. This was considered too extensive to resect, and nothing was done. The clot was found in the right iliac artery. The patient was put on an intravenous drip, which was continued for seven days, and then a rectal drip for three days. Complete starvation by mouth was ordered. At the end of ten days the patient—to my surprise being still alive—was given an injection of pituitrin 0.5 ml. and a turpentine enema, with an excellent faecal result and the passage of flatus. For several days things went smoothly, the bowels acted on alternate days with enemas, and she took a gradually increasing amount of food by mouth. On the sixteenth day abdominal pain and tenderness were felt just above the caecum; her temperature rose to 100° F. (37.8° C.) and a slow perforation with localization was suspected. She was put on penicillin for four days, when the temperature subsided and the abdominal pain abated. She vomited several times. At the end of a week she seemed out of danger. She took light invalid solid diet, and the bowels responded to liquid paraffin and cascara. The tender mass gradually decreased in size, and after a month she went home. The patient remains well after six months.

Case 4.—Mr. H., aged 70. Hitherto a fit man requiring no medical attention, he had two days' history of abdominal pain, vomiting, and constipation. Examination showed a dirty tongue, slight distension of the abdomen, and localized tenderness over the right iliac fossa. Blood pressure was 230/120. A diagnosis of appendicitis was made. At operation the appendix was found normal; there was free blood in the peritoneal cavity, and ecchymoses of the caecum and a short length of ascending colon pointed to local occlusion of a mesenteric vessel. The abdomen was closed and an intravenous drip set up. Heparin was used in the drip, which was continued for three days, and complete starvation by mouth was insisted upon. Pituitrin 0.5 ml. and a turpentine enema resulted in a good bowel movement and passage of flatus. Light food by mouth was now taken, and the patient rose from bed on the eleventh day. He made normal progress as from a laparotomy.

Case 5.—Miss T., aged 74. This case is most interesting, as the patient had two attacks. The first ended in complete recovery (following laparotomy) for thirteen months. At the second attack there was partial recovery, but death resulted from a subsidiary cause. Originally she complained of abdominal pain with vomiting for four days. There was vague tenderness in the centre of the abdomen, but no disturbance of temperature or pulse, and the bowels responded to enemas. Laparotomy disclosed an extensive

occlusion affecting the upper two-thirds of the small intestine. Nothing operative could be done, so the abdomen was closed and an intravenous drip established. No food or drink by mouth was allowed, and a Ryle's tube was left *in situ* for several days, with frequent aspirations of stomach contents. This was continued for ten days. Pituitrin 0.5 ml. and a turpentine enema were given, and faeces and flatus were passed. The Ryle's tube was withdrawn and the drip discontinued. Liquids by mouth, and then solids, were allowed. Gradually recovery ensued; the abdominal distension slowly subsided, and the patient was as well as she had been for years.

After thirteen months the symptoms returned and were an exact repetition of the previous attack: vague abdominal pain with persistent vomiting. She went to a nursing home, and, being confident of the diagnosis, I did not advise laparotomy. She was treated as before with a Ryle's tube (which sometimes withdrew up to four pints (2.3 litres) of faecal matter), and an intravenous drip (later replaced by a rectal drip owing to difficulty with her available veins). After ten days the pituitrin and a turpentine enema produced a good result. She began to take fluids by mouth, but this time her convalescence was much impeded by vomiting and tremendous distension of the abdomen. Unfortunately she developed an ulcerative stomatitis with cervical lymphadenitis and parotitis. She was given penicillin, which controlled the accompanying fever, and pus was aspirated from the abscess that formed in the submaxillary region. She made a gallant fight for seven weeks, and seemed to be definitely better, with no vomiting for the last two weeks. Then she suddenly died from heart failure, apparently due to toxæmia. Post-mortem examination showed the same area of the bowel to have been affected—the upper two-thirds of the small intestine. It was still distended to twice the normal calibre, and the walls were cyanotic and thin. No accurate estimate of the state of the vessel could be obtained as examination was very difficult.

Discussion

In two cases (Nos. 3 and 4) the area affected was the large intestine, and one can understand how an anastomosis could be established by collateral vessels. In Case 5 a great length of small intestine was involved; on both occasions of occlusion recovery took place, although the intestine as seen at necropsy was still poor in appearance and performance. How did the length of bowel recover? In both the large-intestine cases the diagnosis made beforehand was appendicitis, presumably because of the localized tenderness over the distended caecum. In Case 2 and Case 5 mesenteric occlusion was diagnosed before laparotomy.

The choice of treatment at laparotomy would seem to be along the following lines. In large-intestine cases, if the intestine is not too gravely affected, expectant treatment is justified even if resection be thought practicable. In small-intestine cases resection should be carried out unless the amount of intestine involved is too great or the patient's condition makes it impossible. As much as 19 ft. (5.85 m.) of small intestine has been successfully removed.

Summary

The case reports of five patients with mesenteric occlusion are discussed. The possibility of the success of expectant treatment, particularly when the large intestine is affected, is emphasized.

To secure the full use of the services of all available specialists, in view of the needs of the National Health Service, the Secretary of State for Scotland has informed the principal hospital authorities concerned that he is willing to meet the cost of additional full-time specialists at salaries up to £1,000. The approval of the Scottish Department of Health is to be obtained in each case. The Secretary of State will expect hospital boards to co-operate with the post-graduate organization of the appropriate university in making an appointment. The Department's approval will be given on the understanding that each appointment and the conditions attached to it are subject to review once the National Health Service is established. These arrangements are a development of the scheme set up by the Scottish universities and the Department of Health, under which ex-Service doctors training as specialists are appointed to special training posts in hospitals with salaries paid by the Department.

REITER'S DISEASE

BY

C. R. BAXTER, M.B., Ch.B., M.R.C.P.

Physician, Hillingdon County Hospital

The recent article by Jackson and the case report by Wrigley on the syndrome known as Reiter's disease (*B.M.J.*, 1946, 2, 197, 199) will no doubt have stimulated clinicians to review in retrospect a number of hitherto obscure cases. It will be remembered that the disease is characterized by the triad of non-specific urethritis, arthritis, and conjunctivitis, with the occasional accompaniment of keratoderma blennorrhagica, haematuria, and diarrhoea.

A. M. H. Gray in his article on keratoderma blennorrhagica (*Med. Annu.*, 1941) quotes Epstein as associating this disease with inflammation of the joints and eyes and discussing its relation to psoriatic arthritis, believing the two conditions to be distinct; for, whereas psoriasis more usually appears on knees and elbows and sometimes on trunk and extremities, the lesions of keratoderma are entirely confined to soles and palms. This view, he goes on to point out, is further confirmed by Taylor, who describes the condition as one secondary to severe polyarthritis and posterior urethritis of gonococcal origin. Gray further quotes Combes, Dietrich, and Cohen, who, after minutely describing the skin lesions, point out that the arthritis is not of the more usual monarticular variety seen in gonococcal infections but a polyarthritis which involves chiefly knees, ankles, wrists, and acromio-clavicular joints, and which, further, shows less than the usual periarticular oedema and inflammation.

Reports of cases of Reiter's disease are so few that the occurrence of a case which in retrospect fits closely into the clinical picture would appear to justify its publication.

Case Report

The patient was an English soldier of 41 who was admitted to Hillingdon County Hospital on Dec. 12, 1945, with the following history. Until the beginning of August, 1945, he had been in perfect health and had not—and in this he is to be believed—run the risk of venereal infection. About Aug. 1, while serving in Norway, he developed an acute conjunctivitis, which became purulent within a short time and for which he received local treatment. He was repatriated on Sept. 6 and admitted to another hospital, where the conjunctivitis, still acute, was treated with penicillin drops. A few days after his admission an acute purulent urethral discharge made its appearance; he had never had such a thing before. Repeated examinations of the discharge failed to reveal the presence of gonococci, and serological examinations were likewise negative. Parenteral penicillin resulted in complete disappearance of the discharge in five days; nor was there any recurrence. Three months after the onset of the conjunctivitis the patient developed an intra-ocular haemorrhage in the right eye, and a few days later iritis in the same eye. The iritis ran its usual course of ten to twelve weeks, and settled down only to recur after his admission to this hospital, as will be described later.

Four months after the original conjunctivitis joint symptoms were first complained of, the ankles, knees, and shoulders becoming stiff but exhibiting no signs of redness or swelling. Not until two weeks later was the first sign of swelling noted—in the second left metacarpo-phalangeal joint—and the temperature for the first time was found to be above normal. At approximately the same time that joint symptoms first became manifest a scaly eruption of the soles was observed.

On Dec. 12 the patient was admitted to this hospital, and his condition was then as follows. He was somewhat thin, and arms and legs showed wasting consistent with a prolonged stay in bed from subacute arthritis. The ankles were swollen and painful and only slightly red; the knees were stiff and painful but not swollen; the left shoulder and elbow were in a similar condition, and the only other affected joint—the second left metacarpo-phalangeal—was swollen, slightly red, and very painful. There was a thick scaly eruption of both soles, which was misdiagnosed as psoriasis in spite of the absence of other skin lesions, and under the free edges of the oails of some of the fingers was a collection of dry cheesy material. The conjunctivae were slightly inflamed, but there was no crusting of the lids. The right eye showed signs of old iritis, with a fixed irregular pupil and posterior synechiae. There was no urethral discharge and the urine was normal. Examination of the other systems was negative, but the E.S.R. was 106, and the gonococcal complement-fixation test and Wassermann reaction were both negative. The temperature on admission was normal.

A course of "myocrisine" was started on Dec. 31, to which response was satisfactory in that, the day after each inject increased pain was experienced in the affected joints, and a but steady improvement in mobility and pain took place so two months later the patient was once more able to walk. S then there has been no relapse, and on Sept. 13, 1946, the sign of trouble is a persistence of some swelling and stiffness of metacarpo-phalangeal joint.

A recurrence of iritis of the right eye took place on Jan. 31, resolving in the course of ten weeks with the help of hot bath and instillations of atropine, "protargol," and other eye drops. May 8 the left eye developed iritis, which resolved in about 6 weeks. At the time of the last examination, on Sept. 13, there was no sign of inflammation in either eye, although synechiae persist.

The scaly eruption of the soles continued *pari passu* with the lesions, and at one time it caused considerable distress from foul odour arising from the layers of dead skin. Treatment with Condy's-fluid baths and the use of a detergent ointment resulted in some improvement, but as the joints cleared so did the skin, now there is no trace of it on the soles; under three nails on hands there is a small collection of dry cheesy material.

During the first twelve weeks after admission he ran a slightly irregular temperature—never above 98.8° F. (37.1° C.).

The patient has recently been readmitted to have an operation for hammer toe, and, apart from the few signs mentioned above, he now shows no trace of the illness which started just over a year ago. Weight and colour have returned, and he looks forward to being able to restart work soon.

Comment

The interest in this case lies in the exhibition of all symptoms of the disease except for the diarrhoea and haematuria, as well as in the sequence in which the symptoms manifest their appearance—conjunctivitis, urethritis, then polyarthritis and keratoderma coincidentally, with recurrent iritis as a concomitant. In view of the complete clearance of symptoms and signs as reported in other cases, it is doubtful if the treatment given in this case had any effect if we except only rapid clearance of the urethral discharge with penicillin.

I have to thank Dr. W. Arklay Steel, medical director Hillingdon County Hospital, for permission to publish this report.

Medical Memoranda

Perineal Suture in Obstetric Practice

In my practice the patient is generally delivered lying in the left lateral position, even when delivery is instrumental, as it is easier when one is single-handed. In this position, satisfactory as it is for the delivery, visualization and suture of a perineal laceration are difficult, since the raw edges tend to fall together and it is far from easy to locate the upper end of the vaginal part of the tear. In an attempt to solve this difficulty the method described below has been evolved. The basis of the technique is insertion of two deep-tension silkworm-gut sutures placed longitudinally on each side of the perineum before delivery of the child. The insertion of these sutures is made near the edge of the second stage in such cases as (1) where perineal laceration may be expected; (2) where episiotomy is necessary; (3) where there is marked stretching of the perineum.

TECHNIQUE

Two semi-curved Hagedorn needles are threaded with strong silkworm gut. The area round the perineum is thoroughly sterilized by washing the part with biniodide solution. The index and middle fingers of the left hand are inserted into the lower third of the vagina, and then separated in fanlike manner in order to protect the presenting part and also to draw the perineum forwards. The needle is inserted through the perineal skin about 1/4 in. (6 mm) from the midline and 1/4 in. from the muco-cutaneous junction, the point passing deeply into and through the vaginal mucosa. The needle then travels within the vaginal cavity, re-entering the deep tissues 2 in. (5 cm.) nearer the vaginal vault and emerging through the perineal skin 1/2 in. (1.25 cm.) above and lateral to the anus. With the vagina the suture lies on the mucous membrane and the lower end traverses the muscles surrounding the anus. The suture is repeated on the other side of the perineum, and both stitches are secured by clamping the free ends of the silkworm gut with artery forceps. With these stitches in position the delivery of the child is completed. Should a laceration have taken place or an episiotomy been necessary the inspection of the wound and the estimation of its extent can easily be carried out by traction on the two lateral

sutures. Access to the depth of the wound is made easy, and the insertion of catgut sutures for the repair of the vaginal mucosa and deep muscles made relatively accurate. After the catgut sutures have been inserted and tied the skin is closed by tying the free ends of the silk worm sutures.

COMMENTARY

The value of this technique lies in the fact that (1) it renders the single-handed repair of an episiotomy or laceration moderately easy; (2) the sutures are in place should laceration occur; (3) if there has been no laceration or episiotomy, but considerable stretching of the parts has caused injury to the deeper tissues, these separated deep tissues are held together by the sutures.

I am aware that self-retaining retractors have been devised to facilitate perineal repair. These are more satisfactory when stitching is done with the patient in the dorsal position, but their use also implies introduction of instruments into a fresh wound in that area.

Broomhill, Selkirk.

D. CHARTERIS GRAHAM, M.B., Ch.B.

Transverse Rupture of External Auditory Meatus

Recent reports in these columns of minor but interesting and unusual injuries prompt me to record a case of traumatic transverse rupture of the external auditory meatus. I have not previously heard or read of this injury. In the present case the nature of the causal trauma was no doubt a shearing force transverse to the line of the meatus.

CASE HISTORY

A girl aged 9 was knocked down by a motor car. In the casualty department a small and superficial cut behind the right auricle was cleansed and sutured, and the patient was admitted to the ward for observation in case of intracranial injury. No evidence of serious injury was found, however, but blood was seen to be escaping from the right auditory meatus. Examination with the auriscope revealed a complete annular laceration of the skin tube at a depth of 5 mm. from the bottom of the concha. The inner part of the meatus had retracted and was visible only as a small circular skin edge, round which lay the damaged supporting cartilage. Repair was undertaken under general anaesthesia. The cut behind the auricle was reopened, excised, and extended, and then deepened anteriorly so as to expose the divided ends of the meatus (see Fig. A). After excision of all tags of tissue, including loose pieces of cartilage, the ends of the skin-cartilage tube were found to fit neatly together and were sutured with five fine catgut stitches, passing through skin and subcutaneous tissue (Fig. B). Sulphanilamide powder was

Showing the external meatus (A) before and (B) after repair

inserted, and the retro-auricular wound closed with a small rubber dam drain through its lower end. A flavine-in-glycerin pack was inserted into the now continuous meatus. Healing took place rapidly and without sepsis, and a slight tendency to stenosis was subsequently treated by repeated dilatation.

DOUGLAS R. K. REID, M.D., F.R.C.S.,
Dunedin Hospital, New Zealand. Surgical Registrar and Tutor.

A Case of Reiter's Disease

Practically all the articles on Reiter's disease during the past three years have appeared in American or Canadian medical journals. I understand from colleagues that cases with symptoms that correspond to the recognized syndrome of polyarthritis, urethritis, and conjunctivitis are not rare in this country, especially in V.D. departments, but as very few cases have been recorded the following typical case may be of interest. As an allergic reaction to bacillary dysentery may be the cause in some cases (Reiter's original case was associated with diarrhoea and blood in the stools), it is interesting to note that this patient had not had diarrhoea in the year preceding the onset of his illness, during which time he had been in this country.

CASE HISTORY

The patient, an Englishman aged 34, served in various parts of the Middle East from November, 1940, to January, 1945, when he returned home. He had three mild attacks of diarrhoea during that time.

was no blood in the stools, and he was not admitted to hospital. He believes he had conjunctivitis in both eyes in December, 1944, which persisted for about two weeks. A dental abscess developed in December, 1945, and a tooth was removed on Feb. 5, 1946. In January, 1946, he experienced pain in the left side of the back, and a week later there was a slight urethral discharge, but no dysuria or frequency. The following day he had conjunctivitis of both eyes. Two urethral smears showed many pus cells and some mixed organisms, but no epithelial cells or Neisserian organisms. He denied any chance of exposure to venereal infection before the onset of his illness. Non-gonococcal urethritis was diagnosed, and a course of sulphathiazole (27 g. in all) was given. Ten days after the onset of the urethral discharge his right ankle became swollen, and a few hours later there was swelling and pain in the left knee. Next his back became stiff, and pain and stiffness in the shoulders, elbows, and fingers began; none of these latter joints became swollen. He was admitted to hospital on Feb. 9, two weeks after the onset of the urethral discharge.

On examination he was seen to be a well-developed adult male. He had severe bilateral purulent conjunctivitis. There was some pain and stiffness in the lumbar region on movement. The right ankle was red, hot, and swollen. There was some limitation of flexion of the right knee but no swelling. Movements of the arm-joints were full, but he could not flex the fingers of the right hand owing to pain. His oral temperature was 101° F. (38.3° C), pulse rate 100, and respirations were below 20; his pulse was regular. The blood pressure was 130/85. The throat was clean, and the teeth showed no obvious sepsis. There were no abnormally enlarged glands and no sign of abnormality in the chest or abdomen. Smears from the eye swabs showed a few polymorph pus cells but no organisms, and cultures were sterile. The blood count showed: haemoglobin, 14.8 g. %; R.B.C., 4,640,000; W.B.C., 6,800 (polymorphs 66%, lymphocytes 34%). He was given sod. sal. and sod. bicarb., 33, 30 gr. (2 g.) four-hourly, and the eyes were treated with irrigations and atropine instillations. On Feb. 11 the B.S.R. was 75 mm. per hour. The urine contained a fair amount of pus; a stained deposit showed a few Gram-positive diplococci. He continued to run a mild pyrexia of 99 to 100° F. (37.2-37.8° C). On Feb. 22 the prostatic smear was crowded with polymorph and epithelial cells. Only a very few staphylococci were seen in the fresh smears. The urethral discharge was very scanty by this time. Next day he was given 200,000 units of penicillin in beeswax and peanut oil. He had no further urethral discharge after this. During the next two days there was a definite improvement in the eye condition, but the temperature and joint pains remained unaltered. Sodium salicylate was stopped on Feb. 23. On March 1 the B.S.R. was 74 mm. per hour.

The temperature had not settled by March 9, and he was still getting pains in the left lower back and across the shoulders and some pain and stiffness in the legs. Penicillin, 30,000 units intramuscularly, was given, followed by 15,000 units three-hourly. This was continued for six days, when a total of 645,000 units had been given. The temperature was not affected and the pulse rate remained at between 80 and 100. On March 13 the blood showed Hb, 13.3 g. %; R.B.C., 3,720,000; W.B.C., 8,100 (polymorphs 66%, lymphocytes 29%, monocytes 4%, eosinophils 1%). Mist. ferri ammon. cit. was given and he was sent to a convalescent home on the 15th to remain in bed there. The temperature became more settled about the end of March, and early in April it was mainly normal, with occasional rises to 99° F. (37.2° C). The pulse was steady, between 80 and 90. While at the convalescent home he had toothache.

The patient returned to hospital on April 15 complaining of pain in the right shoulder, down the right arm, and in the right ankle. He still had conjunctival injection after sleeping. His blood count now was: Hb, 16.3 g. %; R.B.C., 5,200,000; W.B.C., 7,500. Wassermann, Kahn, and gonococcal complement-fixation tests were negative. B.S.R. 36 mm. Urine: pus cells two per field, no organisms seen. Examination showed slight injection of the left conjunctiva. Right ankle: full movements, but skin reddened over the outer part. He still complained of pain in the right ankle, but skiagrams revealed nothing abnormal. On April 22 he complained of some tenderness in the left ankle and slight puffiness. He still had toothache, and a skiagram on the 26th showed some bone infection near the root of $\frac{1}{2}$. On May 2 $\frac{1}{2}$ and $\frac{2}{2}$ were extracted under gas. B.S.R. 30 mm.

On June 9, four months after admission, he was feeling better, but still had occasional joint pains and slight conjunctival injection in the morning. B.S.R. 9 mm. Urine: no albumin, no pus, blood, or casts, no organisms seen. He started to get up, and sulphacetamide ointment was applied locally to the eyes, without improvement. He was discharged from hospital on June 28. The temperature was normal, rising very occasionally to 99° F. (37.2° C), the pulse rate between 70 and 90, and the B.S.R. 8 mm.

He was seen on three occasions as an out-patient, the last time on Oct. 26—nine months after the onset of his illness. He still had some mild aching in the joints, especially of the right arm and right ankle, and also occasional pains in the lumbar region and the back of the neck, which varied with the weather. A skiagram of the right ankle showed no evidence of structural change in the joint. He had no urinary symptoms, but was still getting slight injection of the eyes on waking. B.S.R. was 8 mm. per hour.

I wish to thank Dr. Ronald McD. Cairns, who was in charge of the case, and at whose suggestion I have written it up, for permission to publish this report.

Reviews

DIGITALIS

Digitalis and other Cardiotonic Drugs. By Eli Rodin Movitt. (Pp. 204; illustrated. 30s.) New York and London: Oxford University Press. 1946.

The use of digitalis is attracting increasing attention in the United States at the present time to judge from the appearance of a second monograph within a few months of a first. This second book contains a frontispiece showing the beneficial effect of "cedilanid" on the x-ray appearance of the chest of a patient with rheumatic heart disease and congestive heart failure. Cedilanid is the name given to lanatoside C, which is a glycoside obtained from digitalis lanata, and which on further breakdown (loss of glucose and of an acetyl group) gives rise to digoxin. In part Dr. Movitt's book reads like a benediction on cedilanid, and a suspicious mind might think the book represents successful propaganda on behalf of this substance. Cedilanid is discussed with enthusiasm in 24 pages, while digoxin is discussed in 3½ pages, in which it receives no bouquets whatever.

A foreword is written by William Dock, who, together with Tainter, demonstrated the action of digitalis in causing constriction of the hepatic vein in normal dogs as a result of which there is a fall of venous pressure. The author is at pains to state that Dock and Tainter do not consider that the action of digitalis in congestive failure is to be explained by this action. Nevertheless, increasing interest is being shown, especially by clinical workers, in the possibility that in congestive failure the action of digitalis is exerted not on the heart itself but on the vessels elsewhere. Thus there appears to be no doubt from the work of McMichael and Sharpey-Schafer, which confirms the earlier observations of Steward and Cohn and also of Ryland, that in the normal human subject digitalis causes a fall in cardiac output and a fall in right auricular pressure. The fall in cardiac output must be a consequence of the fall in right auricular pressure, and this in its turn must be the consequence of some change in an organ or in a vascular area away from the heart. In the patient with heart failure, however, digitalis causes the same change of pressure in the right auricle, but this is attended by an increase in cardiac output, and therefore both effects are more likely due to an improvement of the heart's action. It is very easy to demonstrate the increased force of contraction of the failing heart when digitalis is administered to the heart-lung preparation of the dog. It is clear, however, that it will be some time before agreement is reached on this subject.

Dr. Movitt's book deals not only with digitalis but also with the glycosides of strophanthus and squill. The literature has been widely studied and the exposition is interesting.

PEPTIC ULCER

Peptic Ulcer. Its Diagnosis and Treatment. By I. W. Held, M.D., F.A.C.P., and A. Allen Goldbloom, M.D., F.A.C.P. (Pp. 382; illustrated. \$6.50.) Illinois: Charles C. Thomas. 1946.

This book is written by two New York consulting physicians. It might well have been built up out of a series of lectures to students or graduates, and it gives a rather static picture of ulcer. Successive chapters deal with aetiology, pathology, diagnosis, and treatment. The various complications of peptic ulcer and the surgical treatment are dealt with fully. There are many excellent reproductions of x-ray photographs but little about the gastroscopic appearances of peptic ulcer in activity and healing. The survey of the material tends to be compendious rather than critical. The problems of diet and treatment with alkalis are not handled in a scientific manner, whereas a number of bizarre and unorthodox remedies are mentioned. The authors tell us very little about the natural history of peptic ulcer and there is no statistical information about the effects of different treatments on its course. Hardly anything is said about the secular changes in incidence of peptic ulcer or the social pathology and psychology of the disease. An immense amount of good British work on incidence, haemorrhage, perforation, psychological factors, differential diagnosis of ulcer from nervous dyspepsia, alkaline treatment, and a variety of other topics

has escaped the notice of the authors. The book is extremely well produced and printed, and is reasonably priced, but it is not one we can recommend. It is twenty years behind the times for readers in this country in both matter and approach.

NATIONAL HEALTH INSURANCE

National Health Insurance in Great Britain, 1911-1946. By R. W. Harris. (Pp. 224. 12s. 6d.). London: George Allen and Unwin Ltd.

Anything on this subject coming from the pen of Mr. R. W. Harris demands respect. As a young Civil Servant he was in at the beginning of our National Health Insurance legislation and took a very active part in its early administrative stages. When he retired from the Service he continued his practical interest in it as chairman of the London Medical Services Subcommittee. He is well known as joint author of *Medical Insurance Practice*, which for many years has been the valued guide of all insurance practitioners. His present book covers a much wider field, for it surveys the whole of National Health Insurance as it at present exists—its sources, its inception, its evolution, its anomalies and difficulties, its successes and failures. His facts can always be relied on, and his opinions are always temperate and founded on knowledge and practical experience. It is a pity that the war prevented the publication of this book six years ago, for it is possible that a study of it by those responsible for the imminent developments in National Health Insurance might have learned from it some useful lessons in how not to do it—lessons which were painfully learned by Mr. Lloyd George and his staff.

Every aspect of the system is clearly described and analysed. Part I deals with "National Insurance"; Part II with "National Health." Our system was "made in Germany," but we were by no means the first country to follow the example set by Germany in 1893. Mr. Harris shows, however, that Germany owed much to the pioneer work of British friendly societies, and that the benefits they had gradually built up for their members grew out of the desire of the British working man to provide a decent burial free from any help from the Poor Law. Mr. Harris clearly shows how the decision of Mr. Lloyd George to use the friendly societies and trade unions in the administration of our system led to many complications and anomalies, all of which are examined in detail. He comes to the conclusion that in spite of these, as an organized scheme for the payment of money during sickness and disablement it has been "an unqualified success." He does not feel so sure about "its value as a contribution to the general health and welfare of the community." His reasons for this reservation are very similar to those which have been presented, without success, by the B.M.A. to one Government after another. This part of the book has a bearing on the prospects of the extended National Health Insurance now before the country. Mr. Harris has at any rate the satisfaction of knowing that finance and health are to be separated administratively, as he has advocated for some years. If this book has, through no fault of its author, been deprived of its opportunity of full usefulness in influencing a further stage of National Health Insurance it can at any rate claim to be a valuable contribution to the social history of our country.

AN AMIABLE AUTOCRAT

Men, Medicine, and Myself. By S. Vere Pearson, M.D., M.R.C.P. (Pp. 254. 12s. 6d.) London: Museum Press Ltd. 1946.

It would be unfair for anyone to complain that Dr. Vere Pearson's "apologia pro vita sua" is too full of his political prepossessions or of tuberculosis "shop," for the title of it gives everyone due warning of what to expect. To his friends (and everyone who has met him is, or wants to be, one of them) this frank record of his career in medicine, of his achievements at Mundesley Sanatorium, of his interest in agriculture, sociology, oecology, and so forth, reveals him just as they have known him. It is no inconsistency that first made him an ardent Labour Party propagandist (though he admits he never believed in Socialism) and then led him to disillusion and dislike of all politicians—red, pink, or blue—but rather the reaction of a generous nature compelled first of all by his sympathies with under-dogs to champion their cause, and then by his intellect to realize that some remedies are worse than the social diseases for which they are prescribed.

To his colleagues in the profession, especially his contemporaries, the first chapters, which deal with his early days in medicine, his adoption of tuberculosis as a specialty in consequence of developing that disease, and his pioneer work in collapse therapy in this country, are of greater interest than the later ones, which are rather for enlightenment of the general public as to hygiene and social problems, especially those connected with tuberculosis. There are many well-told anecdotes about eminent physicians of the older generation, and much that enables those who can look back on the medical world of forty-five years ago to see more clearly than they otherwise might do the problems of that time and the evolution of methods for solving them.

When the author deals with the problems of medical education as he sees them to-day, his suggestions are perhaps more debatable, though there will be many to agree with his comments on what is often called "penny in the slot" diagnosis of disease. At any rate he has, we may be sure, thoroughly enjoyed "getting things off his chest"—which after all is to be expected of an expert in pulmonary lesions. At Mundesley he confesses that he finds it necessary to be an absolute autocrat—though doubtless he does not regard his patients as under-dogs—and it would certainly be interesting to know what his nickname is, to learn whether he has carried there the old sobriquet of student days, "Severe" Pearson, given to him by antinomy as being the very last adjective that could justly attach to him, or whether anyone has thought to call him "Mr. Chips." It is typical of his reticent modesty that he nowhere mentions that he was a rowing blue at Cambridge and a member of one of the outstanding crews of those days.

Notes on Books

All About the Deaf is a handbook compiled by the National Institute for the Deaf (105, Gower Street, W.C.1: 3s. or 3s. 3d. post free). Its forerunner was first issued over twenty years ago. Since that time there has been a great stirring of the public conscience in regard to the needs of the deaf and of the deafened, and this is illustrated in the number of agencies which now exist for their relief and help, and the variety of forms which such assistance takes. The legal provisions which affect the deaf, the education of the deaf and dumb, the work of local authorities on behalf of the deaf community, the recent developments in hearing aids—these and many other matters are set out so as to convey the maximum amount of information in the most concise form.

The Cardio-pulmonary Function during Pregnancy, by Dr. G. WIDLUND, Supplement I to *Acta obs. gynae scand.* XXV.: (Uppsala) is a symposium valuable both for its original studies and for its comprehensive bibliography of some 300 papers in which there is incidentally, no doubt as a consequence of war, a noticeable shortage of references to recent English and American contributions. The pregnant woman is shown to have an increased oxygen consumption, increased vital capacity, and slight increase in pulse rate and blood pressure, and the material will allow a considered evaluation of the techniques of pneumothorax and pneumoperitoneum. The painstaking study is presented in English and gives one more proof of the liberality of Swedish medical education.

Preparations and Appliances

CHIP GRAFTS IN THE NECK OF THE FEMUR

Mr. F. P. FITZGERALD, F.R.C.S.I., Harley Street, London, W.1, writes:

One of the great difficulties in the treatment of fractures of the neck of the femur by nailing is the delay before union is complete. Some years ago, in an attempt to overcome this, I treated a fairly large series of cases by grafting the neck of the femur with the fibula, alone and reinforced with a nail (*Lancet*, 1943). The results were disappointing. Recently I have utilized chip grafts from the ilium, so far with complete success, and a detailed account of the cases is in preparation. The following is an account of the method and instrument used.

The instrument, or chip graft gun (see Fig. 1), resembles a large trochar and calibrated cannula with a funnel (A and B), and a special hollow auger bit to fit the cannula (C). Two guide

wires are placed in the neck of the femur. A nail is threaded over the upper one in the usual way. The auger-bit is fitted into the cannula, and threaded over the lower guide wire. By rotating the handle a hole is bored in the femoral neck along the guide wire, and the instrument forced into the bone to the required depth, as noted on the calibrated cannula. The auger-

FIG. 1.—A, funnel or hopper. B, graduated cannula with solid plunger or trochar in place. C, hollow auger-bit which fits the cannula.

bit is then withdrawn, leaving the cannula in place. Finely cut chips are then dropped into the hopper, and packed home through the cannula with the solid plunger or trochar. The cannula is gradually withdrawn as the space becomes filled with chips, and the instrument is removed when the cavity has been filled to the outer cortex of the bone. The wound is then closed in the usual way.

The instrument can also be used for extra-articular arthrodesis of the hip-joint.

FIG. 2.—A case one month after operation.

The broken lines in Fig. 2 show the position of the chip grafts.

Nurses' Salaries Committee Notes nos. 12 and 13 have been issued by the Ministry of Health (price 4d. and 2d. respectively from H.M. Stationery Office). The former is concerned with (a) female hospital nurses, (b) male hospital nurses, (c) public health nurses, (d) ex-Service male student nurses, (e) trained nurses: title to increments in respect of service in the Forces, and (f) post-certificate leave for public health nurses; and the latter with nurses variously employed in the public health services. The recommended revised scales have effect from Jan. 1, 1946.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY DECEMBER 7 1946

THE CHEMOTHERAPY OF TUBERCULOSIS

The ever-widening field in which chemotherapy has attained clinical success leaves the few hitherto resistant conditions in increasing prominence. Among these, tuberculosis and virus diseases stand out above all others. There is so far scarcely a hint that the viruses are susceptible to any such attack, and nothing that we know of their properties and behaviour encourages belief to the contrary. In tuberculosis, on the other hand, much has already been done, and those who care to take stock of the situation will find ample material in the Mitchell Lecture by P. D'Arcy Hart, the full text of which is given in the present and preceding issues of this *Journal*. It can rarely have happened that two such notable contributions to the study of a single subject should be made in the same month as this and the Harben Lectures¹ delivered a few days later by W. H. Feldman, of the Mayo Clinic. Both lecturers trace the history of their subject and recognize that present-day developments date from the observation of Rich and Follis in 1938 that the progress of experimental tuberculosis in the guinea-pig is retarded by the administration of sulphanilamide. Thence sprang a series of studies embracing further sulphonamides and, later, sulphones, revealing increasing degrees of therapeutic efficacy in the experimental disease. The origins of antibiotic therapy may be said to go much farther back—more than thirty years ago Vaudremer in Paris treated over 200 cases of tuberculosis with a substance derived from an *Aspergillus*—but the effective study of such substances dates only from the recognition of penicillin as a true chemotherapeutic agent in 1940. Development on these lines has led us to streptomycin, the only antibiotic so far to receive adequate trial, both experimental and clinical, in the treatment of tuberculosis.

Feldman's contribution is notable for its very full description of experimental study, in which he has taken a major personal part. That properly conducted therapeutic trials in animals should precede any sort of clinical trial will be generally recognized: what "properly conducted" means is not so well understood. Feldman lays down rules for therapeutic tests in guinea-pigs which might with advantage be generally followed. The strain of tubercle bacillus used for producing the infection should preferably be a "classical" one available to other workers. There should be two sets of control animals—untreated, and treated by some other agent of known degree of efficacy, such as one of the sulphones. The severity of the test can be varied by varying the quantity of tubercle bacilli with which the animal is inoculated, but still more by extending the period which elapses between inoculation and the beginning of treatment. The agent has the best chance if administration is begun at

once. The severity of the test can be progressively increased by delaying treatment for any period up to seven weeks by which time disease is well advanced. This may be verified by a tuberculin test or even by liver biopsy before treatment is started. Feldman also provides a scheme for assessing the extent of disease in numerical terms, taking into account not only gross but histological findings. The extreme test—freedom from disease of such an organ as the spleen—is tested by inoculation with it of another animal. What sulphonamides and sulphones on the one hand, and streptomycin on the other, will do is clearly set forth in his paper, both diagrammatically in terms of gross lesions and numerically in terms of his system of scoring. The sulphones, notably promazine, do much: their "suppressive" effect—meaning arrest of the progress of the disease without actual elimination of the organism—is prolonged, even when treatment is delayed for six weeks; but they do not eradicate the infection, and the disease progresses when treatment is stopped. Streptomycin on the other hand, when administration was begun at the same time, appears actually to have cured a large proportion of animals: in 52% there was "no discernible tuberculosis either gross or microscopic"; some had ceased to react to tuberculin when finally killed, and in 7 out of 10 such negative reactors the spleen was non-infective to other guinea-pigs. Similar results were obtained with many strains of tubercle bacilli, and with the bovine as well as the human type. They were also obtained, when treatment was begun 23 days after inoculation, regardless of whether the daily dose of 4 mg. was given in four, two, or one daily injections, or even in doubled quantities daily during alternate weeks. Whether this surprising result means that streptomycin can be given infrequently to patients instead of according to the usual 3-hourly schedule is a question which is not discussed. Feldman also records, in tabular form, the results of treating 75 tuberculous patients with streptomycin. The most striking item in this list is the survival of 4 out of 7 patients with meningitis. In other categories assessment is naturally more difficult, though a majority in most are judged to have shown a favourable response.

We must turn to our own pages and the wider outlook of D'Arcy Hart for a more comprehensive account of what is going on now, and for a far-sighted appreciation of future possibilities. For those not fully apprised of the scope of modern tuberculo-chemotherapeutic work his list of chemical compounds, with a statement of their activity—*in vitro*, in the experimental, and in the human disease—against *Mycobacterium tuberculosis* will be astonishing. These compounds fall into no fewer than five categories, and although of very unequal merit they embody two strictly rational lines of approach: an active compound may conceivably either enter and attack the organism by virtue of lipid-solubility or it may block an essential synthesis. The latter approach appears to be the more promising, but in the absence of more clearly defined knowledge of the metabolism of *Mycobacterium tuberculosis* there is no certainty that a substance acting in this way exists. Another equally formidable list of potential chemotherapeutic agents, their activity in many cases being still largely unexplored, is that of the antibiotics. Here we are on purely empirical ground, and D'Arcy Hart's prophecy—that the approach from this direction and from the study of synthetic chemical compounds

backed by some hypothesis as to their possible mode of action will ultimately meet—is perhaps looking rather a long way into the future. Apart from a few agents derived from such peculiar sources as garlic, a lichen, toadstools, and streptococci, substances inhibiting the growth of the tubercle bacillus have been obtained chiefly from *Aspergilli*, *Actinomycetes*, and *Bacilli*. Some of these are known to be too toxic for clinical use; others have not yet been tested *in vivo*; and hundreds of others doubtless remain to be identified. Certainly no other agent is yet known to approach streptomycin in therapeutic efficacy; on the other hand, streptomycin is not the ideal beyond which no one may hope to go. Its clinical efficacy cannot be finally assessed, but it is certainly not absolute. Some toxic effects are now being observed after heavy dosage; and the fact that in some patients tubercle bacilli recovered after a course of treatment have exhibited a thousandfold increase in their resistance to streptomycin must be a bad augury.

The discussion of the future outlook with which the lecture concludes emphasizes some of the difficulties with which the work contends. One is only comparative—the very leisurely pace at which everything proceeds where the tubercle bacillus is concerned: *in vitro* and *in vivo* experiments take weeks and months, whereas with most other bacteria they are a matter of hours and days. More formidable is the series of barriers, in the tissues and perhaps in the tubercle bacillus itself, which any effective agent must penetrate. It is encouraging to hear the view expressed that these difficulties have perhaps been exaggerated. On the other hand, the difference between the experimental disease in the guinea-pig and its more chronic form in man is distinctly to the disadvantage of the latter. It is perhaps noteworthy in this connexion that the success of antibacterial chemotherapy as we know it now, though its two agents are unrelated, varies in each case directly with the acuteness of the disease, and with the rate of multiplication of the infecting organism. Chronic infections, whether because the organism is multiplying less actively or because it is protected by the surrounding tissue reaction, are more resistant both to sulphonamides and to penicillin. If it is legitimate to apply this finding to the field of tuberculo-chemotherapy the result is not encouraging. On the other hand it is, fortunately, reasonable to hope that in a semi-resistant animal such as man treatment which does not produce complete sterilization of the lesion may yet achieve a large measure of success.

RESEARCH IN TROPICAL MEDICINE

Few engaged in medical research or practice in the Tropics but will acknowledge a debt of gratitude to the many activities and helpful publications of the Liverpool School of Tropical Medicine. Founded in 1898, and now not far from its fiftieth anniversary, the School has been second to none in the wealth of research it has carried out or in the extent and usefulness of its publications. A record of what the School has achieved during the six years of war, recently published, gives evidence of its valuable work during this critical period. Under the late Prof. Warrington

Yorke's energetic organization the Liverpool School has provided courses of instruction in tropical medicine for medical officers of the Army and Navy attended by approximately 2,000 officers. Additional classes were given at the request of the War Office for R.A.M.C. pathologists, and at the request of the Chief Surgeon of the United States Army for members of the U.S. Army Medical Corps waiting to be drafted to tropical areas. Publication of the *Annals* was continued under considerable difficulties, 175 papers appearing from 127 different authors between September, 1939, and December, 1945. In the six years of the war the staff of the School contributed more than 90 papers to scientific journals besides many secret reports for Government Departments and Committees. In the wards over 1,000 cases of amoebic dysentery were treated. In West Africa the staff of the Sir Alfred Jones Laboratory at Freetown, at the request of the Sierra Leone Government, took over the greatly expanded pathological service at this large wartime naval and shipping centre.

Members of the Liverpool School staff have as individuals and as representatives of the School served on many committees and bodies concerned with the progress of the war effort. Prof. Yorke was appointed a vice-president of the Anglo-Soviet Medical Union in 1941, and shortly before his death went to the United States on a commission on the vital matter of improving the prospects of adequate supplies of mepacrine—in which he was brilliantly successful. In 1940 and again in 1944 Prof. D. B. Blacklock at the request of the Colonial Office returned to West Africa to investigate and advise upon the menacing malaria situation in the West Coast ports. Researches in many urgent matters relating to the war have been extensively conducted. Undoubtedly the most striking event in this respect has been the discovery of the antimalarial drug paludrine, which promises to solve some of the most difficult features of drug prophylaxis in malaria. During the war experience showed that mepacrine as a prophylactic was capable of changing the whole outlook on malaria prevention in a tropical campaign. But even mepacrine was not a completely satisfactory drug, and search for the ideal drug has been actively carried out in the war years both in this country and in America. Among compounds submitted for test by Imperial Chemical Industries there was discovered at the Liverpool School in 1942 an entirely new range of chemical substances having a therapeutic action on the malarial infection of birds, and early in 1943 one of these drugs—No. 2666—was tested on human cases. This and the compound No. 3502 were, however, not very effective, but further compounds of the series were successively tried, including Nos. 3349 and 4430, which were about as effective as quinine or mepacrine, until finally No. 4888 or paludrine was reached. Tested in human malaria by Adams, Maegraith, and their co-workers, this was found not only to arrest acute attacks of both benign and malignant tertian but to be devoid of any side-effects. Judging from the results reported elsewhere obtained by Fairley in Australia, it would appear that paludrine is eminently suitable for prophylactic use, since it does not, like mepacrine, produce yellow coloration, is extremely non-toxic, and even taken one day in the week appears to be an effective prophylactic.

Among other important researches that have been made are investigations of the action of different diamidines in kala-azar, trypanosomiasis, and babesia infections, on an epidemic of sleeping sickness in which these drugs were successfully used, on acquired drug resistance, and on the treatment of scabies and its control by the use of 5% tetmosol soap. The report includes a tribute to the memory of Warrington Yorke, whose outstanding contributions to chemotherapy have brought fame to himself and the School. It is gratifying to read that response to the appeal for the Warrington Yorke Memorial Fund had up to the end of 1945 led to contributions and promises under deed of covenant of £46,530 towards the capital sum of £60,000 asked for.

THE CLOSED MIND

What has this country come to when a Medical Officer of Health is compelled to dismiss from hospitals under his control nurses and doctors because they will not join trade unions—and this at a time when hospital beds have to remain empty because there are not enough nurses to go round? Yet this is what has happened at Willesden. The matron, the deputy matron, 36 nurses, and one doctor of Willesden Municipal Hospital, and the matron, resident medical officer, and 11 certified State midwives at Willesden Council's maternity hospital, Kingsbury, were last week given one month's notice. This notice of dismissal was, according to the accompanying letter from the Medical Officer of Health for Willesden, "in view of the fact that you have not complied with the Council's resolution regarding membership of a trade union." Seventy nurses and a number of probationers at Walthamstow Council's two hospitals have just been notified that they must join a recognized trade union or organization: this notification was tactfully handed to them along with their pay packets. According to a statement in the Press, the Medical Officer of Health for Walthamstow said: "We have given the nursing staff a list of nine professional organizations which they may join, such as the Royal College of Nursing and Nalgo." Heston and Isleworth Borough Council decided at its last meeting "that all employees shall be members of their respective trade unions, provided that such unions be affiliated to the T.U.C. or eligible for affiliation thereto." The Gateshead Council has also decreed that all its employees should become "members of an appropriate trade union," and Gateshead teachers are up in arms about it. These fresh bungles of Bumbledom are fortunate because their crass folly has drawn on them the wholesome publicity of a Press which still remains free. The next scene in "Insanity Fair" will, no doubt, be the refusal of the authorities to admit patients to hospitals unless they have a trade union ticket.

At Willesden, the sister tutor and deputy matron had been serving at the hospital for 24 years and the night sister for 26 years. Two of the staff nurses had given their faithful service, one for 20 and the other for 28 years. Yet these women were given a month's notice because they

would not conform to a requirement which had no relation to their function or capacity as nurses who care for the sick. It is no exaggeration of language to describe such treatment as outrageous. They have, along with their fellow nurses, stoutly refused to accept a position which is intolerable to them as free individuals practising a humane and self-sacrificing profession. Miss Ward, matron of one of the Willesden hospitals, said in a statement to the Press: "The staff will do their duty, but I cannot guarantee, with the feeling there is among the staff, that they will all remain after this. . . . The staff are more determined than ever that they will not join a union." The stand taken by the Willesden nurses will, it is suggested, compel the borough's General Purposes Committee to withdraw the notices of dismissal, and it is believed that the Committee will recognize the Royal College of Nursing.

Though Willesden may wriggle out of the ludicrous situation in which it has placed itself there still remains unsettled the issue of compulsion by local authorities on their medical and nursing employees to join a trade union or recognized professional organization. Dr. F. R. Ellis stated in a letter published in the *Supplement* of November 23 that in answering an advertisement in the *Journal* for a full-time medical officer at a borough council—it was Willesden—he received with his application form a notice which included this statement:

"That trade union membership be a condition of employment of all persons continuing in or entering the service of the Council, and that present employees who are not members of a trade union be advised of this decision and given a reasonable time—i.e., by Nov. 1, 1946—in which to join a trade union."

At a meeting of the Council of the B.M.A. on November 6, 1946, it was explained that local authorities were requiring employees (1) to be members of a trade union or professional association, (2) to be members of a trade union, but accepting membership of "Nalgo" as satisfying the condition, or (3) to belong to a trade union affiliated to the T.U.C. The Association immediately appointed a Committee to investigate the position, and the matter will be discussed once more at the next meeting of Council. In the meanwhile, the Secretary of the B.M.A. has stated that "In the view of the B.M.A., no doctor should be required to join any body, the B.M.A. or other. Membership should be a voluntary act. Wherever a local authority imposes a condition of trade union membership the Association will advise the profession not to apply for appointments under such an authority." A statement of the attitude of the B.M.A. in relation to the position in Willesden and other areas, and the steps it proposes to take, will be made after the meeting of the Council on Dec. 11.

The medical profession is to-day independent, and the majority of its members are free to choose their way of life and livelihood. When officialdom exercises its petty tyrannies we can resist with effect and safeguard the professional liberties of doctors in whole-time employment. But when the whole profession is in the employment of the State where will be the safeguards? Willesden is a disturbing sign of the modern menace—the "closed mind."

PENICILLIN IN ACUTE MASTITIS

There is probably no malady which causes more suffering to the mother than acute mastitis at a critical time in her life and that of her baby. Treatment has so far proved unsatisfactory, especially in the case of the mother who is in her own home, suffering perhaps from severe pain, struggling to keep the household going and to look after a young infant. Even in hospital the various methods of treatment in current use have proved far from ideal. For these reasons, and because treatment with the sulphonamides has proved disappointing, treatment with penicillin opens up great possibilities. The primary infection appears to be almost invariably due to *Staph. aureus*, an organism not generally very sensitive to sulphonamides but sensitive to penicillin.

In this issue of the *Journal* Lady Florey, Mr. MacVine, and Miss Bigby describe the treatment of breast abscesses with penicillin, giving the results in 18 cases and comparing them with those of 16 control cases treated with sulphonamides. It was found that in the penicillin-treated cases there was a significant reduction in the duration of pyrexia and suppuration and a decrease in the healing time. Penicillin was given at first systemically by intramuscular injections of 15,000 Oxford units every three hours. As soon as fluctuation was detected, or when the abscess appeared to have localized and was small, pus was aspirated and penicillin injected into the abscess cavity, under local analgesia—120,000 units in some cases and 500 units in others. It was found that under treatment pus gradually disappeared and was replaced by sero-sanguineous exudate. A culture was made from this fluid, and if *Staph. aureus* was absent no further treatment was necessary. It was found that 4 to 7 daily local injections were required. Sinuses developed very readily in penicillin-treated cases, and penicillin was instilled along the track of the sinus after expression of pus or, in other cases, by a needle inserted until a sinus formed and then along the track of this sinus. Abscesses containing more than 10 ml. of pus were incised and drained, and penicillin was instilled twice daily after expression of pus. The importance of complete expression or aspiration of pus before injection or instillation of penicillin is emphasized. Suckling is continued, and the authors consider the administration of stilboestrol unnecessary.

In a recent article in this *Journal*¹ Mary D. Taylor and Stanley Way describe the use of penicillin in 10 cases of acute puerperal mastitis. Treatment was started early, the indications being pyrexia associated with flushing and hardening of the breast, or in some cases pyrexia with pain in the breast. Systemic injections were given, but details of dosage are not stated, only the total doses, which varied from 300,000 to 1,050,000 units. Suppuration occurred in only one case, and all were cured in seven days, 6 out of the 10 patients being cured in three days or less. These authors recommend that suckling be temporarily discontinued if it causes discomfort, and that in these cases a small dose of stilboestrol (not more than 1 mg. in 24 hours) be given. The breasts are kept empty.

Penicillin is now within reach of every practitioner in adequate quantities, and it seems that it should prove very valuable in treating acute mastitis and in preventing and treating breast abscesses. Treatment should begin as soon as possible and penicillin should be given in adequate doses. In domiciliary practice three-hourly injections are difficult, but good results can be obtained by giving two or three injections of 100,000 units or more per day. Use of the oily solution prolongs the effect. Taylor and Way recommend stilboestrol where there is flushing and discomfort, but advise only a small dose. Lady Florey and her

colleagues are opposed to this, but they do not say why: perhaps it is because they do not wish to inhibit lactation. It has been found, however, that if suckling is continued stilboestrol in small doses does not generally inhibit the production of milk, though it does often help to diminish vascular engorgement and discomfort.

A partial solution has been found for a problem which has long proved difficult and distressing for those entrusted with the care of puerperal patients and mothers who are feeding their babies. It is to be hoped that the use of penicillin will not only diminish suffering from mastitis but will help to increase the incidence of breast-feeding.

PENICILLIN SYNTHESIS

The ending of the official secrecy with which the laboratory synthesis of penicillin has hitherto been invested compels some attention, even if the achievement proves of no more practical importance than as an entry in future textbooks of biochemistry. Penicillin was first synthesized more than two years ago by the Oxford team, of which, as is generally known, Sir Robert Robinson is the senior chemist. At about the same time—and it is presumed independently—synthesis was also achieved by the Merck organization in New Jersey. The yield was, however, only about one-tenth of 1%; and in addition the synthesis was not of such a kind as to be chemically informative. No attempt was therefore made by the Oxford workers to prepare synthetic penicillin in chemically pure form by this method. Instead, later efforts have been directed, so far without success, towards the development of a further synthesis of greater practical utility. Subsequently a second American team, working in the Department of Biochemistry of Cornell University Medical College, applied the original method of synthesis to produce a small supply of chemically pure penicillin II. The Oxford synthesis was of penicillin I. But since the method, within its obvious limitations as to yield, is generally applicable to all the penicillins, the distinction is of no significance. The present paper, which is of a preliminary character, is the work of the Cornell team—Du Vigneau, Carpenter, Holley, Livermore, and Rachele. It is published in *Science* of Nov. 8, the journal of the American Association for the Advancement of Science, with due credit to the earlier work both at Oxford and in the Merck laboratories. Authority for publication in this form was given by the joint Anglo-American committee which is responsible for the release of information on the work which has been carried out for the Committee on Medical Research of O.S.R.D. in the United States and the Medical Research Council in Great Britain. The result takes us little if any further as regards knowledge of penicillin, but among the general public in the United States it has given rise to the erroneous impression that the first synthesis of penicillin was a purely Cornell achievement.

REITER'S DISEASE

The symptom complex known as Reiter's disease—conjunctivitis, arthritis, and urethritis—appears to be a definite disease entity, though reference to standard textbooks provides little or no information on the subject. The condition was first described by Reiter¹; and soon afterwards Fiessinger² in France and Macfie³ in Africa recorded some cases. Most of the earlier cases occurred in France, Germany, and Scandinavia. Little more was heard of the condition for some years, but recently other cases have been reported, including ten from the Pacific area and six

² *Bull. Mém. Soc. méd. Hôp.*, Paris, 1916, 40, 2030.

³ *Parasitology*, 1917, 9, 274.

from Boston; and Vallee,⁴ in a review of the literature, refers to 151, while Touraine and Ruel⁵ put the number at about 300. The latter authors call it "pseudo-gonococcal enteritis," whereas Sargent⁶ proposes the term "idiopathic blennorrheal arthritis."

Almost all the described cases are in males (usually young); there is no relation to sexual intercourse. Some French observers consider that the condition is associated with dysentery or other intestinal infections. In the light of recent war experience Paul Wood,⁷ Marsh,⁸ Herson,⁹ Kay,¹⁰ and Manson-Bahr¹¹ all correlate the disease closely with bacillary dysentery, but Jackson¹² shows that no identification with these bacilli has yet been made and that his two cases developed in an area where bacillary dysentery was unknown. The conjunctivitis is purulent or mucopurulent, and often bilateral; there is some photophobia and lacrimation; and there may be scleritis, iritis, and keratitis as well. The urethritis is characterized by a purulent discharge, but frequency and dysuria are not as marked as would be expected, though haematuria may occur. The arthritis affects mainly the larger joints, flitting from one to another, and imitating acute rheumatism; hydrarthrosis is common. In addition there is usually a low-grade fever. Skin rashes often appear; they start as vesicles which rupture and form shallow ulcers, and these heal leaving hyperkeratotic scars. Harkness¹³ records three cases which resembled keratoderma blennorrhagica. Generalized lymphadenitis is a frequent accompaniment; there is a moderate polymorphonuclear leucocytosis, and the erythrocyte sedimentation rate is slightly increased. All three typical signs are not always present, and consequently the differential diagnosis may be from rheumatic fever, gout, acute conjunctivitis, prostatitis, balanitis, keratitis, iritis, non-specific urethritis, and arthritis.

The causal organism was thought by Reiter to be a spirochaete, but this has not been confirmed. Harkness claims to have demonstrated inclusion bodies, but modern opinion inclines to the view that a virus is the probable causal agent. Pathological examination of the urethral and conjunctival discharge and of fluid aspirated from the affected joints has failed to incriminate any particular organism. The gonococcus has never been found. Blood cultures are uniformly negative, as are gonococcal complement-fixation tests, serum tests for syphilis, and agglutination tests against dysentery and typhoid bacilli. Treatment is mainly symptomatic, though some success has been claimed with sulphonamides and arsenicals, as well as with protein-fever therapy—it seems not unlikely that artificially induced pyrexia by means of a Kettering hypertherm or similar appliance may be beneficial (King¹⁴ *et al.*). It may be noted that two of Fieldsend's¹⁵ cases diagnosed as abacterial pyuria had arthritis. Were they cases of Reiter's disease? If so it is of interest to observe the favourable response of the urethritis to neoarsphenamine. The disease is self-limiting, though it is apt to drag on for several months, and relapses are not uncommon.

Cases recently reported in this *Journal* by Wrigley¹⁶ and Jackson¹⁷ are of interest as showing that the disease is probably not nearly so rare as has been supposed. The combination of urethritis with arthritis has led to many cases falling into the hands of the urologist or the venere-

ologist. This combination is so common in gonorrhoea often with conjunctivitis as well, that the practitioner can hardly be blamed if he makes a provisional diagnosis gonococcal, or at any rate of infective, arthritis, though he will be saved from the former error if he has the benefit of and faith in, adequate pathological facilities such as culture examinations and complement-fixation tests. Denfield,¹⁸ as a result of observation of its association with gonorrhoea in West Africans, hints at an allergic origin of the syndrome, as it requires more than one attack of gonorrhoea to provoke it, and, when provoked, subsequent attacks of the acute urethritis successively intensify the Reiter disease.

WORLD LIST OF SCIENTIFIC PERIODICALS

Active preparations are being made for the issue of a third edition of the *World List of Scientific Periodicals*. The last edition of this invaluable scientific reference work was issued in 1934 and covering the years 1900–33, is now out of print though still in constant demand. It contains upwards of 33,000 titles of journals and includes the holdings of some 180 libraries in Great Britain and Ireland. The new edition, which is designed to include all the scientific and technical periodicals that appeared during the period 1900–47 as well as the holdings of additional libraries, will therefore be considerably larger. Librarians are being asked to co-operate as before by sending particulars of all the journals on their shelves that do not appear in the second edition, or are shown there as having no location in the country, to: The Secretary, World List of Scientific Periodicals, c/o The Zoological Society of London, Regent's Park, London, N.W.8. Further information may be obtained from this office.

Sir Arthur MacNalty will give the FitzPatrick Lecture before the Royal College of Physicians of London on Dec. 10 and 12 at 5 p.m. His subject is the History of State Medicine in England: Lecture 1, "From the Accession of Queen Victoria to the General Health Board"; Lecture 2, "The Medical Department of the Privy Council".

The President and Council of the Royal Society have awarded the Copley Medal to Prof. E. D. Adrian, O.M.D., for his researches on the fundamental nature of nervous activity, and more recently on the localization of certain nervous functions.

¹⁸ *British Medical Journal*, 1946, 2, 555.

Col. Malcolm Stoddard-Scott, M.D., Conservative M.P. for Pudsey and Otley, has presented to the Minister of Health a memorandum urging that Bradford hospitals should be classed as teaching hospitals under the National Health Service Act. The memorandum was prepared by a committee of local authorities in Bradford after considering in detail the requirements for a medical faculty in that city. In the committee's view Bradford could provide accommodation, teachers, and clinical material for a medical school and could from October, 1947, train 50 undergraduates a year. A letter to the Minister Col. Stoddard-Scott informs him that the Bradford Technical College already trains undergraduates for the first part of the London M.B., and is recognized by London University for that purpose. If a medical school is established in Bradford it would be prepared to train undergraduates for the final M.D. of London and Leeds Universities, and would also admit students wishing to take the English and the Scottish conjoint examination and those for the licence of the Society of Apothecaries. Medical and surgical work under the scheme would be carried out in the Bradford Royal Infirmary, St. Luke's Municipal Hospital, the Royal Eye and Ear Hospital, the Children's Hospital, the City Fever Hospital, the Bierley and Grassington Sanatoria, and the Rawdon Rehabilitation Centre.

ADAPTATION OF E.M.S. HUTS FOR CHILDREN'S WARDS

BY

WILFRID F. GAISFORD, M.D., F.R.C.P.

Consulting Paediatrician

AND

C. H. ELKINS, L.R.I.B.A.

County Architect, Warwickshire County Council

In the report of the British Paediatric Association's *ad hoc* committee on cross-infection in children's wards, published in the *B.M.J.* (May 4, 1946, p. 673), sections 6 and 7 deal with the subdivision of wards and other desiderata. With the recommendations of this report in mind, we prepared a plan to show how a typical E.M.S. hutted ward may be modified at reasonable cost and with minimal structural alterations to accommodate infants and children in surroundings where the chances of cross-infection are lessened and other desiderata are provided.

Just after the preparation of our plan, the Ministry of Health published a series of plans, including one for a children's ward, prepared by Dr. T. S. McIntosh and Mr. H. R. Coales, on the adaptation of E.M.S. huts for peacetime hospital purposes (Supplement to the *Monthly Bulletin of the Ministry of Health*, February, 1946). Our plan is not intended to rival or better

theirs; indeed, Dr. McIntosh and Mr. Coales point out that it is all to the good that different methods of adaptation should be explored.

Figs. 1 and 1a show the proposed adaptation and the existing E.M.S. hut in Warwickshire, respectively. Figs. 2 and 2a are reproduced from the Supplement to the *Monthly Bulletin*, by permission of H.M. Stationery Office, for comparison.

E.M.S. huts vary, and the type chosen by the Ministry is admittedly the most difficult to adapt architecturally, with its flat roof and central supporting pillars. It differs structurally from those existing in Warwickshire County Council hospitals in the following details:

Fig. 1a (Warwick)

Pitched roof 35°
Floor to eaves in ward, 10 ft. (3.05 m.)
Ceiling, 12 ft. 8 in. (3.86 m.)
Four pairs of doors in each long wall

Fig. 2a (Ministry)

Flat roof with central columns in ward
Ceiling, 10 ft. 1 in. (3.07 m.)
Two pairs of doors in each long wall

Arrangement of Ancillary Rooms

Overall length, 36 ft. 4 in. (11.07 m.)
Ceiling, 9 ft. 8 in. (2.95 m.)
Corridor, 5 ft. wide (1.52 m.)
Sluice, 9 ft. 1 in. (2.77 m.) by 8 ft. (2.44 m.), adjacent to W.C.s.
Kitchen adjoining ward, with observation window
No store-room
Small heating chamber for domestic hot water, towel rails, and radiators

Overall length, 40 ft. (12.2 m.)
Ceiling, 8 ft. 1 in. (2.46 m.)
Corridor, 6 ft. wide (1.83 m.)
Sluice, 9 ft. 7 in. (2.91 m.) by 8 ft. 7 in. (2.62 m.), adjacent to ward
Sentry near entrance
Store-room, 8 ft. 7½ in. (2.63 m.) by 7 ft. (2.13 m.)
No heating chamber. Hot water presumably from central service

EXISTING WORK
NEW WORK

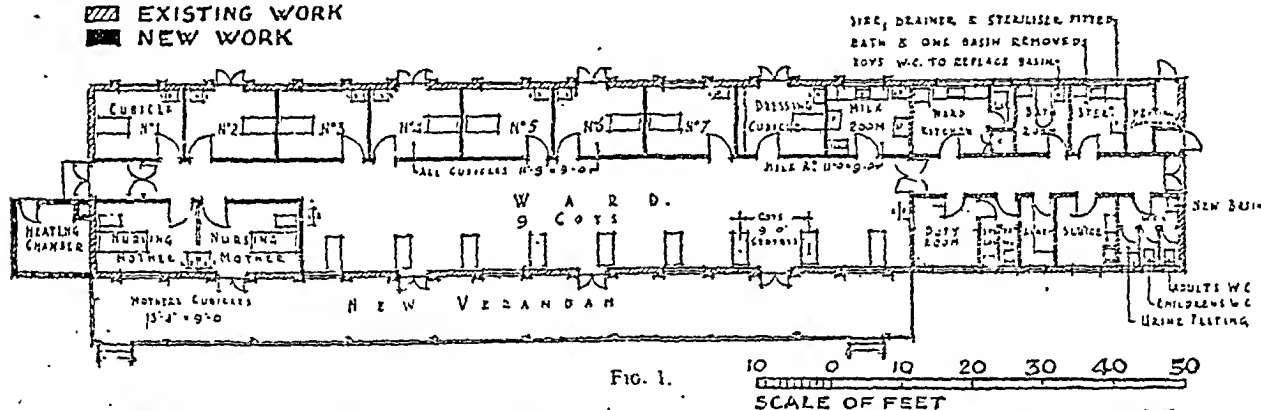

FIG. 1A.

Plan showing typical 32-bedded hutment adapted to provide a children's ward with protection against cross-infection. FIG. 1.—Plan after alteration; accommodating 7 cots in separate cubicles, 9 cots in open ward, 2 cubicles for nursing mothers, 1 cubicle for dressings. Cubicles to have plug point and lavatory basins in each. FIG. 1A.—Plan before alteration—32 beds.

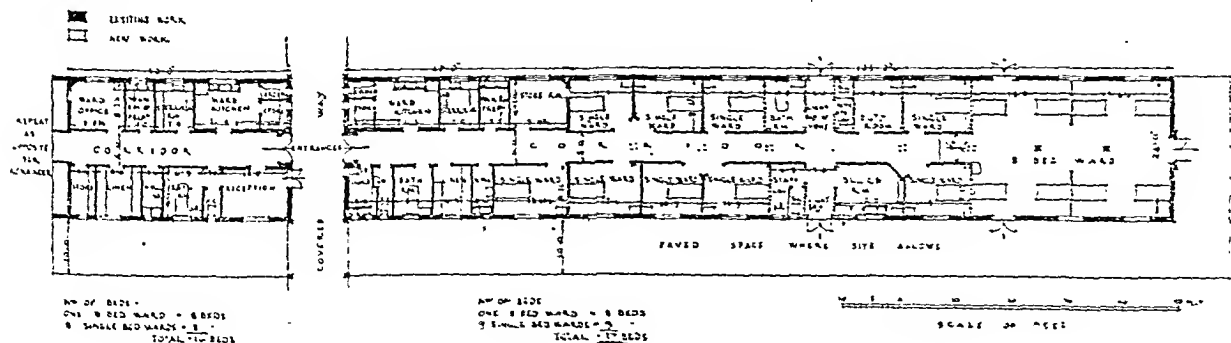

FIG. 2.

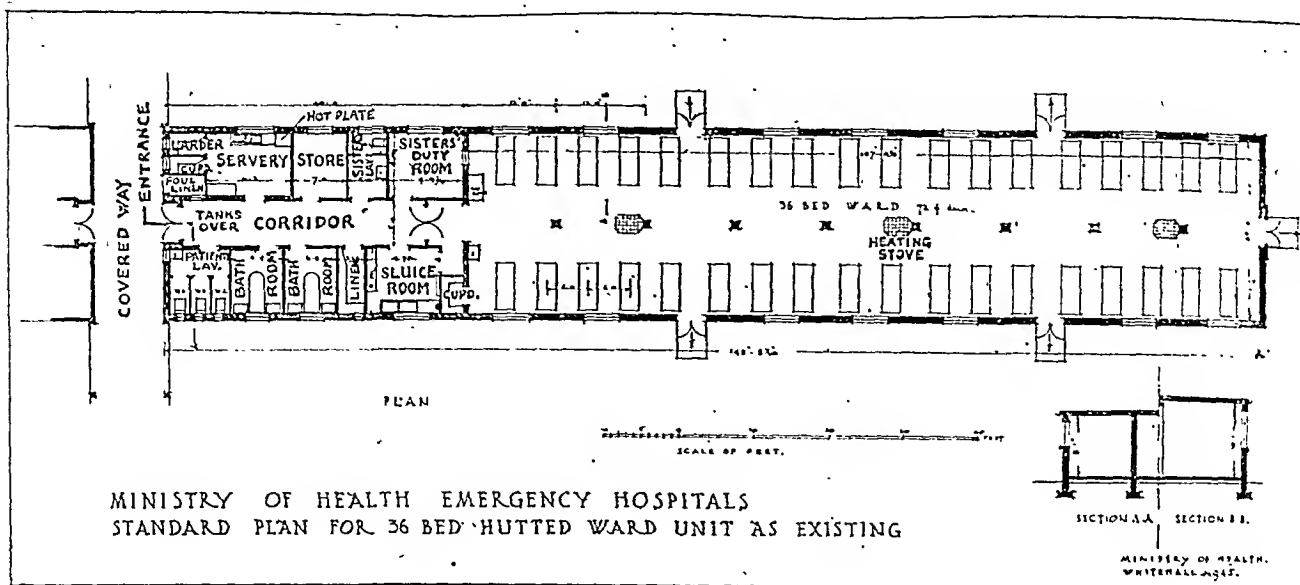

FIG. 2A.

The total length and breadth of each ward are the same—viz., 108 ft. (33 m.) by 24 ft. (7.3 m.), so that the differences are really of a minor nature and chiefly limited to the ancillary rooms.

The ward as existing has accommodation for 32 patients. By subdividing it into cubicles (Fig. 1) this number is reduced to 18. Seven of the cubicles are single, which provides a percentage for isolation considerably higher than the 25% minimum recommended by the subcommittee. The 9-bedded open ward allows of a friendly communal atmosphere for older children, who do not need the strict isolation that is necessary for young infants. It should be a rule that no infant under 1 year of age is to be admitted to an open ward. It will be seen that there are two cubicles provided for nursing mothers and their infants. When there are no breast-fed babies in the ward these cubicles could of course be used as single cubicles for children, or two infants could be nursed in each, bringing the total beds available up to 20. (The word "cot" in the plan refers equally to a child's bed.) The existing heating arrangements consist of three centrally placed coke-burning stoves. These are not suitable for a children's ward, and we have substituted an outside heating chamber.

One of the subcommittee's special points was the desirability of having a separate room in which to do surgical dressings,

lumbar punctures, aspirations, etc., and this is provided. There is also a small room for testing urines. The milk-room, which is 11 ft. (3.35 m.) by 9 ft. (2.74 m.), is more adequate in size than the one proposed by the Ministry, which is only 8 ft. 7½ in. (2.63 m.) by 5 ft. (1.52 m.). In our plan, the ward and all the cubicle doors can be under direct supervision from the duty room.

The Ministry's plan allows for a store-room 9 ft. 9 in. (2.97 m.) by 8 ft. 7½ in. (2.63 m.), a housemaid's closet, and an additional sluice. This arrangement of a sluicing compartment and lavatories in the central part of the ward is advantageous from the point of view of access, but we wished to undertake a minimum of structural alteration in our plan, in which cost was also taken into consideration. We think one bathroom would be sufficient, but if necessary the end bed in the open ward might be sacrificed and a small bathroom, lavatory, and sluice included for the use of the nursing mothers. The other modifications in the ancillary part of the ward are as outlined in the plan.

Summary

A plan is suggested for the adaptation of a typical E.M.S. hutted ward for the accommodation of 7 babies in single cubicles, 9 children in an open ward, and 2 nursing mothers with their infants, together with a room for dressings, a milk kitchen, and the other usual ancillary offices.

SOCIETY OF APOTHECARIES AWARD TO PENICILLIN DISCOVERERS

At a special meeting of the court of the Society of Apothecaries of London on Nov. 28 Sir Alexander Fleming and Sir Howard Florey were presented with the Society's gold medals in therapeutics in recognition of their discoveries in penicillin. The presentation was made by Dr. C. Thackray Parsons, the Master, in the presence of a large number of freemen and of guests, who included Sir Alfred Webb-Johnson, President of the Royal College of Surgeons, and Sir Hugh Lett, President of the British Medical Association. The Master referred with pride to the addition of these names to those of Dixon, Gowland Hopkins, Dale, Banting, and others on the Society's roll of medallists. "In the nurseries of the future the contaminated Petri plate of Fleming will probably displace the legend of Newton and the apple, and as future generations eat their prophylactic breakfast of mixed moulds they will pray for the good estate of Fleming and Florey."

Prof. E. C. Dodds, in a brief oration, compared the present occasion to the gathering at the Sorbonne in 1892, when Pasteur on his seventieth birthday was acclaimed by the President of the French Republic and a distinguished company which

included Lister. In the work of Fleming and Florey they saw one of the last acts in the drama which opened with the work of Pasteur. The veil of mystery which for centuries had covered the processes of infection had been rent, and an uncertain empiricism had given way to scientific principle. Never before in the history of the world had it been possible to honour two men who had been personally responsible through their labours for the fact that literally millions of people to-day were alive who would otherwise be in their graves, and, unlike many brilliant discoveries of science, not even the most malignant mind could suggest that this discovery could be applied in an offensive or destructive manner.

Sir Alexander Fleming, in receiving the medal, said that it had been his good fortune—he emphasized the word "fortune"—to be in at the beginning of a movement which had done something for medicine and surgery. He contrasted the conditions obtaining in the first world war with those obtaining in the second from the particular point of view of fracture of the femur. In 1918 he was in charge of a hospital for cases of fractured femur, and it was a grim experience, very different from that which attended these cases during the recent war. Not all the difference, of course, was due to penicillin, but it helped. He paid a warm tribute to his co-recipient.

Sir Howard Florey also spoke of his own good fortune in being associated with Sir Alexander Fleming in a work which had proved of value in medicine. The experience had been for him particularly exciting, because it had given him the opportunity of travelling all over the world and of meeting thousands of people. Coming as he did from a young country (Australia), he perhaps more than those in England appreciated the antiquity of the hall in which they had met and the general setting of the ceremony. He added that they were only just beginning to realize the extraordinary series of fortunes with which this work on penicillin had been favoured. There were 100,000 species of moulds such as those that rotted timber or grew in the fields; there were 15,000 species of *Ascomycetes* to which penicillium belonged, and there were several hundreds of species of penicillia. Many of these produced chemical substances and, almost without exception, they were extremely poisonous. Yet penicillin was the first one to be examined in any detail, whereas it might well have been one of the other thousands of organisms, and they might have endeavoured to extract the active substance and, realizing that it was extremely poisonous, have abandoned the investigation.

Occasion was also taken to make a presentation to Mr. W. T. Withers, who is retiring from the position of bedel of the Society after fifty-nine years' service.

ROYAL COLLEGE OF SURGEONS AND THE ACT

SPECIAL MEETING OF FELLOWS

A special meeting was held at the Royal College of Surgeons of England on Nov. 29 following upon a requisition made by a number of Fellows and Members at the Annual Meeting of the College earlier in the month. The purpose was to consider the position which has arisen consequent upon the passing of the National Health Service Act. Sir Alfred Webb-Johnson presided and there was a very large attendance.

The Council's Corporate "Yes"

The President said that in the College they had always done their best to approach this question non-politically. They regarded the freedom of the profession, not as a vested interest, but as guarding one of the fundamental rights of a citizen in a free country. They had contended that the Negotiating Committee should be supported because it was representative of the whole profession; they had always resisted attempts to undermine its authority, and they had desired to support their general practitioner colleagues. Four important points affecting general practice remained in the Act, notwithstanding the endeavour to get them removed: prohibition of the sale and purchase of practices; restriction on the individual practitioner as to where he should practise; the setting up of a tribunal (with final appeal only to the Minister) which had power to decide that a practitioner should no longer remain in the Service; and remuneration by basic salary (this last not in the Act but in the White Paper and in the intention of the Minister).

Personally he confessed that he did not think any of these items sufficient ground for refusing to discuss the implementation of the Act and the planning of the Service. The most important was the salary element in the remuneration of general practitioners, which might undermine the doctor-patient relationship. On principle he thought it undesirable, but he recognized that a considerable number of young men would welcome such an arrangement. In hospital practice the most serious thing was that the Act created a monopoly of hospital surgery. That might have serious effects, but he did not know that they could refuse to discuss the Act with the Minister because he was taking over the hospitals. By negotiation it might be possible to induce him to frame regulations whereby the patient would be left with as much freedom as he had at present. It was undesirable that the Minister should be empowered by regulations to control the fee charged for all patients admitted to the paying blocks of hospitals; it was said that the ceiling would be high, but that was not the point. The point was that in some of the accommodation in the private wings of hospitals there should be complete freedom of relationship between doctor and patient, though he agreed

that in some portion of such accommodation there should be some control so that people of moderate means might be able to be accommodated privately. What might be obtainable by negotiation was the preservation of independent practice. That was an important thing for a free profession.

"I have fought for all these things," Sir Alfred Webb-Johnson concluded, "at the stage when the law was in the making. Considerable concessions have been obtained during the passage of the Bill; I believe considerable concessions may be obtained in the form of regulations. The Council has to answer in a corporate capacity the question whether it desires the Negotiating Committee to enter into discussion on the framing of such regulations. As a corporate body the Council has answered 'Yes.' As individuals it is for each of us to make up his own mind."

Runnymede or Munich?

Mr. Lawrence Abel opened for the opposition. He quoted resolutions of the Council of the College, especially those of May 8 last, expressing opposition to certain proposals which were then in the Bill and now remained in the Act. He also quoted from the reported speeches of the President of the College, warmly supporting the case of the general practitioners and protesting against State monopoly and other dangers. It was said that the Act was only the bones of the scheme and the regulations would clothe this skeleton with flesh. But the "bones" were ill conceived, they were worm-eaten and decalcified, and the more flesh that was put on a rachitic skeleton the greater would be the deformity. He asked the Council of the College, "Are you going to let your Fellows down?" If they were convinced that their principles remained sound they would answer "No" in this plebiscite. Was this to be their Runnymede or their Munich?

Mr. W. Etherington-Wilson said that he had come up from the West Country with the expectation of his colleagues that he would return with the assurance that at all costs the Royal College of Surgeons was going to stand rock-like for the principles which the profession had established.

A New Act of Uniformity

Mr. Reginald T. Payne said that the question now was whether the profession was to negotiate on regulations. Regulations would not alter the principles of the Act, but only its details. The implications of this Act were far wider than its application to the medical profession: they opened up important constitutional and legal considerations. Was a Government department to be entrusted with the powers which this Act conferred on the Minister? Further, was a monopoly of medicine justified in a democracy? If they answered these questions as members of a liberal profession their duty and responsibility to the community would take them far away from merely personal or professional answers. The catchwords of the age were "organization" and "efficiency," but these could be gained at too great a sacrifice of freedom. In Italy under Fascism the trains ran much more punctually, but intellectual and political liberty disappeared.

Mr. Payne entered upon a lengthy discussion of constitutional aspects. All parliamentary business was now extremely hurried, which meant lessened parliamentary control and a greater dependence on regulation. The judiciary was short-circuited. This Act was an outstanding example of delegated legislation. Quasi-judicial bodies were gradually being developed in this country—bodies which often sat in *camera*, and from whose findings there was no appeal. Under this new Act there could be no appeal to the courts by any dismissed doctor. It also created a State monopoly of medicine. It was an Act of Uniformity for the better discipline of doctors and patients. The consultant would be "directed," it would be a case of "join the Service or be liquidated." The student would be "grant-aided, State-conditioned, and rendered servile, mobile, and docile." What about the Royal College? In ten years' time half the Council would be civil servants in all but name and the other half would be Government pensioners. If this Act was operated it would be necessary to restart independent institutions in the interests of the public and of medicine. Fundamental democratic rights would have to be re-established and reasserted. In a democracy there must be a right to dissent.

His own sympathies for many years had been with the Labour Party, but he was terrified by the position into which

they were now forcing the community. The crisis was comparable with that of the seventeenth century on the issue of liberty versus the tyranny of central power. Then it was a question of kingship and religion, now it was a question of the executive and political and social theory. He begged them to stand for their essential freedom and not to become Government pensioners with their minds in cold storage. The power which the central organization had in this Act meant coercion and regimentation. The analogy with 1912 was false. We had not then a dictator-ridden world. Of the National Health Service Act he could only use colloquial language and say that it "stinks of dictatorship." It was a whip in the hands of the executive. "You can negotiate, if you are going to negotiate, on how the whip should be used."

A Resolution Not Put

Dr. N. E. Waterfield proposed the following resolution:

That this meeting of Fellows regrets the decision of the Council to recommend members of the College to agree to enter into negotiation with the Minister on the regulations to be made in connexion with the new National Health Service Act, as the decision runs counter to the feeling of the meeting of the Fellows here present.

This was seconded by Mr. Lawrence Abel.

The President said that he was unable to accept the resolution; it stated what was not a fact. The Council had made no recommendation to the Fellows and Members. He had taken the trouble to explain very carefully in his opening remarks that it was for each man to decide for himself.

Dr. Waterfield: I thought you said that the Council had come to a decision in its corporate capacity.

The President: I said that the Council had instructed me what to reply as a College. This meeting has been called at short notice for the purpose of exchanging views. Up to now certain people have monopolized the platform. Is there any contrary view?

Major J. S. Horn said that he thought they should answer "Yes" in the plebiscite. They had been urged to say "No" because it was stated that certain fundamental points of principle were at stake. There were certain points in the Act which they all agreed were bad, but others which they all agreed were good, and it seemed to him of first importance not to confuse points of principle with expediency. He thought that the scheme, which was brought forward by a Government recently returned to power at a general election, should be accepted and the best possible job made of it.

Mr. C. E. Beare said that it was a sad day for him to find himself not in agreement with Sir Alfred Webb-Johnson, for he admired so much the way he had worked for the profession. But the British Medical Association, which represented over 50,000 members of the profession, had instructed its representatives to take a firm stand on certain principles, and those principles had been established by votes of between two and three hundred to an insignificant minority, if not unanimously. Having affirmed those principles, how could they possibly negotiate merely on regulations and terms of service? The report of the Negotiating Committee declared that the independence of medicine was at stake. On a recent Sunday he visited between 20 and 25 doctors in his locality and there was not one "Yes" among them, and at a meeting of 80 practitioners at Reigate there were only eleven affirmatives. The majority included a number of young men who said: "We thought we had been fighting for freedom, and we come back to find dictatorship imposed upon us."

Mr. Dickson Wright said that he was perturbed at the prospect of hospitals being a public monopoly. Free choice of hospital was just as important as free choice of general practitioner. There would be no medical committee in Government hospitals. Consultants would be directed from hospital to hospital in the most unpleasant way. Direction was even more unpleasant for the established consultant than for the young general practitioner, for it was hard to settle down in a new place when one was fifty. A State monopoly of medical treatment would lead to loss of morale in the profession. Doctors were not going to strike, but they were at liberty to say, "We are not going to work for you." When the Government had overstepped its mark there was nothing wrong in

one section of the community making a sacrifice if necessary and putting its foot down and saying, "We are not going to do this, not because we are afraid of having less money, but because we think it is a bad thing. We want free choice of hospitals." He felt strongly that this consultant body should have been recommended to say "No" in the plebiscite.

Mr. Sangster Simmonds said that the result of this Act was not going to depend on the regulations with which they were so much concerned, but on the way in which the medical profession did its work. The success of voluntary hospitals had been achieved because the physicians and surgeons on their staffs had done their work well. The success of this Act would depend on individuals and how they worked, not on Regulations from Whitehall. The old Insurance Act was a piece of legislation which the profession did not help to negotiate but which was forced upon them, yet the profession had made a success of it.

Concurrence with the Main Body of the Profession

Mr. A. J. Gardham said that he found it difficult to say in the same breath that he disapproved of the principles of the Act and that he wished to participate in the framing of its Regulations. He desired to move a resolution on one matter on which he felt strongly:

That with regard to the National Health Service Act the Royal College of Surgeons of England shall take no action which is not in accord with the wishes of the main body of the profession.

Such a resolution might save the College from a disastrous decision.

The President: What do you mean by "the main body of the profession"?

Mr. Gardham: That is a matter we should have to ask the Council to decide.

The President: I was very anxious to avoid putting any definite resolution to this meeting, because this is a meeting called at short notice for the expression of views. Any formal resolution should have been circulated with the notice.

Mr. Gardham said that he had put forward the resolution, not with a view to instructing the Council, but as a means of assuring the profession at large that the surgeons were with them and not against them. (Loud applause.)

The President: Will it satisfy those who have brought forward this resolution and the meeting generally if a notice is sent to the Press stating that it was generally agreed that the College should act in conformity with the general feelings of the profession in regard to the question of negotiations on the regulations of the Act? (General murmurs of assent.) The President added that the Council had told the Negotiating Committee what the College recommended concerning negotiation, but if other members of the Committee did not concur and the general feeling was in a different direction the recommendation of the Council would not carry. Why should he be put in this quandary regarding what the earlier resolution called the "decision of the Council"? It was not quite fair to him.

Dr. Waterfield said that the Council, apparently, was not desirous of knowing the feeling of the Fellows generally. He asked that his resolution should be put.

The President said that the decision of the Council as representing a corporate body was not binding upon any individual. The Council had thought it to be its duty to recommend agreement to enter into negotiations. He did not think it fair, on the strength of that, to be asked to put a resolution to the meeting regretting the action of the Council. Members might not know how difficult and distressing the position of leaders of the profession might be.

Dr. Waterfield said that he was prepared to withdraw his resolution.

The President: Thank you very much. I appreciate your anxiety that the College should take a firm stand. I will convey to the Council the general feeling of this meeting and will include in a communication to the Press a statement that this College will stand loyally by the majority of the profession, whatever their decision may be.

In reply to Mr. T. A. Green, the President said that a considerable majority of the Council had voted in favour of negotiation. What reasons moved them he could not say. It might

have been his persuasive eloquence, though he did not unduly try to influence them. He thought they felt that they were going to get very poor support from the public if at this stage they refused to negotiate, whatever might happen at a later stage. It must be admitted that they had not had a very good Press up to now. He himself held the view strongly that at this stage it was their duty to negotiate.

The meeting then terminated. It was attended by 150 Fellows, and although no vote was taken the volume of applause suggested that there was a large majority against negotiation.

PRIORITY SUPPLIES OF MILK TO INVALIDS

On Oct. 29 the Minister of Food made a statement on milk certification. He implied that there had been laxity by doctors in issuing their certificates and announced that all certificates issued before Nov. 3 must be renewed on or after the 30th of that month unless their time expired before that date. It will be recalled that the matter was discussed at the November Council Meeting and a strong protest issued.

The Minister's announcement was made in the Press, in the *British Medical Journal* (Nov. 2, p. 661), and over the wireless, but this method of notification resulted in a certain amount of confusion. Doctors had not been notified personally, and consequently only those who saw or heard these announcements were aware that certificates must be reissued. The result has been that doctors have been annoyed by frequent demands from their patients for renewed certificates, and patients have been unable to obtain their priority needs of milk.

Practitioners are reminded that patients are unable to obtain their priority supplies of milk unless they submit a certificate issued after Nov. 3.

Reports of Societies

TREATMENT OF ACUTE PERITONITIS

At a meeting of the Section of Surgery of the Royal Society of Medicine on Nov. 6, with Mr. E. F. FINCH in the chair, Prof. JOHN MORLEY said that he would confine himself largely to the diffuse or general infection of the peritoneum rather than deal with the localized abscess. Surgical opinion had passed through various stages since Lister laid the abdomen open to surgery. When surgeons at last put aside their unreasoning dread of the peritoneum their reaction was to treat it with far too little respect for its delicate defence mechanism. At one time there was a great belief in the drainage of the peritoneum, and the abdomen after an operation would be left bristling with tubes. A great step forward from the vigorous and ill-advised flushing was made when gentle sponging of the peritoneum with swabs wrung out of normal saline took its place, later to be replaced by suction. The greatest advance in treatment was the realization of the important part played by dehydration in peritonitis, the loss of water and sodium chloride from the blood, and the practice of replacing this fluid by normal saline given at first by the rectum and subcutaneously and later by the intravenous route. A further step forward came with the introduction of the Ryle tube, and the crowning mercy was chemotherapy. As the vast majority of the cases of peritonitis were secondary to perforations of the alimentary tract, he would put first among the principles of treatment the closure of the ulcer or removal of the appendix. The operation itself, necessary though it was, did inevitably add somewhat to the risk of paralytic ileus, which was in its essence a defence mechanism. He preferred the term "inhibition ileus" as emphasizing the initial state when treatment could do some good; later, when the gut was distended with gas and fluid and oedematous or inflammatory changes had taken place and there was a failing circulation, the wall of the gut became truly paralysed and a stage was reached when the paralysis was irreversible. The fundamental difference between inhibitory or paralytic ileus and mechanical ileus must be emphasized. Peritonitis, of course, often led to mechanical ileus by causing

fibrous adhesions which resulted in kinking, torsion, or compression of the bowel. Operation should be carried out with the least possible trauma, and that was the main reason why, in addition to spinal anaesthesia, an adequate incision and suction should be used rather than sponging to cleanse the peritoneum of infected fluid.

Should the Peritoneum be Drained?

Should the peritoneum be drained? The answer in perforated peptic ulcer was emphatically "No." He had not drained a perforated peptic ulcer, except in an occasional late case with subphrenic abscess, for twenty years; drainage was unnecessary and was likely to give rise to dangerous adhesions. In peritonitis from a gangrenous appendix he seldom drained unless an abscess cavity was present which was prone to bleed, but always drained the abdominal wall if it was heavily contaminated. In general, drainage of the peritoneum did very little good, though when in doubt there was no great harm in draining for a day or two. On the subject of chemotherapy there was still no unanimity as to which was the best drug to use or the best manner of its application. It was bad practice to apply masses of sulphonamide powder within the peritoneal cavity; a much sounder method was to introduce it in suspension in normal saline. It was a matter for discussion whether intraperitoneal applications of the sulphonamides should be supplemented by sulphonamides given by the intravenous route or by penicillin.

Within recent months two vigorous tugs had been made at the pillars of the house of surgical orthodoxy—namely, Spalding's attack on the time-honoured Fowler position and Hermon Taylor's advocacy of the non-operative treatment of perforated peptic ulcer. The belief that Fowler's was the best position to protect the patient from subphrenic abscess formation did not emerge unscathed from Spalding's attack. Without subscribing to all the arguments about the hydraulics of the peritoneal cavity the contention concerning the limitation of breathing when the patient was propped up in the Fowler position was impressive and Prof. Morley felt that Spalding had made out a good case against it. Hermon Taylor's plea for the expectant treatment of perforated peptic ulcer was less convincing. In a patient who was a bad operative risk owing to old age or chronic bronchitis it was preferable to try expectant treatment, but in the average risk, if one got the perforation early—within the first six hours—he would not advise it. It was wrong to regard the present operative mortality as serious. In the last 24 cases of perforation on which he himself had operated there was only one death (of a man who had perforated five days before and had a subphrenic abscess), and in his unit in Manchester Royal Infirmary during the last five years in 100 cases of acute perforation there had been only 8 deaths, all of them in patients who were either bad risks by reason of bronchitis and emphysema or in whom the perforation had taken place more than twenty-four hours before.

Protein Balance

Mr. C. G. ROB said that recovery from established acute general peritonitis, while depending to some extent upon the skill of the operating surgeon, was governed to a far greater degree by the pre- and post-operative care which the patient received, and one factor in ward care was protein balance. From the investigations on protein metabolism during the late war some surprising facts about the easily estimated plasma proteins came to light. For example, the patient with chronic long-standing wound sepsis usually had a normal plasma protein level although considerable protein loss had occurred. In burns or acute peritonitis the plasma protein level might fall before the tissue protein could be mobilized to replace the loss. Patients with established acute general peritonitis suffered from reduction of body proteins which occurred in four principal ways: (1) exudate from the surface of the peritoneum; (2) into the lumen of the distended intestine when paralytic ileus had occurred; (3) into the subserous and serous layers of the peritoneum, and (4) owing to associated reduction of protein digestion. Mr. Rob entered upon a description of the mechanism involved, leading up to a fact of great clinical importance, namely, the need of giving a

plasma transfusion to every patient whose peritoneal infection was severe enough to require an intravenous infusion, thereby maintaining the plasma protein at normal level. Not only would such a procedure prevent the onset of peripheral circulatory failure, but if given in sufficient quantity it might even correct established peripheral circulatory failure in an apparently moribund patient. During the past three years he had treated 31 patients who had established general peritonitis and had placed them on a post-operative regime which included plasma transfusion. In 25 of those who received the plasma transfusion before there was peripheral failure no sign of such failure developed, and all made a satisfactory recovery. The other six did not receive a plasma transfusion until after peripheral circulatory failure had developed. They were moribund, with a very rapid and thready pulse and a subnormal temperature; but in spite of this three of them recovered, due no doubt to the very large amount of plasma they received. Every patient whose peritonitis was severe enough for an intravenous infusion to be necessary should receive plasma as a prophylactic measure against the peripheral circulatory failure to which such patients so often succumbed.

General Discussion

Mr. VAUGHAN HUDSON spoke of the value of penicillin as an auxiliary in the treatment of peritonitis or as a preventive of complications. There was a definite place, as war experience had shown, for parenteral penicillin in all injuries from without. The failure of the sulphonamides to prevent the post-operative complications of pneumonia after collapse of the lung and infections in the renal tract was disappointing; but the control of these complications by parenteral penicillin was encouraging. Mr. NICHOLSON criticized Fowler's position. In a unit with which he had been connected the practice was to have the patient flat on the back, and in that position the subject did as well as in Fowler's position. Many patients did not like Fowler's position, and more harm than good was done by compelling them to be in a position in which they were uncomfortable. Prof. IAN AIRD spoke of the difficulty of estimating the value of the sulphonamides and penicillin in a condition such as peritonitis owing to the absence of a control series. An attempt at a control series was made in the children's hospital in Edinburgh, but the figures obtained were not significant.

Sir HENEAGE OGILVIE said that towards the end of the war nearly every surgeon dealing with abdominal injuries adopted the principle of replacing lost protein by intravenous plasma, but the methods used were very haphazard. It was very interesting to find it put on an experimental basis by Mr. Rob. In peritonitis they were perhaps too apt to be concerned with the bacterial side. Certainly peritonitis was an abscess in the largest cavity of the body, but surely it was a cavity which could deal with infection better than any other. He agreed with Prof. Morley that drainage should not be carried out in a wide general peritonitis; in fact, any local drainage in a widespread infection was almost a waste of time, but he would have thought that a localized abscess should be drained every time. In the presence of an abscess they drained not for the pus they found to-day but for the pus expected to be there to-morrow. In all conditions the forestalling of ileus was one of the most important things to be done. He endorsed what had been said in criticism of the Fowler position. The position was based on "nursery mechanics," and had no support in physiology or animal experiment. Prof. PATERSON ROSS raised the question of morphine in acute cases. It was often taught that a well-localized peritonitis could quite safely be treated by morphine; but it was not safe with a diffuse peritonitis. He could not help thinking that if there was diffuse peritonitis and it was desirable to give the bowel complete rest morphine could be used both with safety and benefit. He added his condemnation of Fowler's position. The obstruction to the return of venous blood from the lower limbs set the stage for thrombosis and increased the risk of embolism. The advantages to the circulation by not adopting the Fowler position were considerable. Mr. DICKSON WRIGHT spoke of the importance in peritonitis of the abstraction of fluid from the general body circulation. He was a great believer in the use of suction. If the body fluids could be shifted a great

deal of good could be done to the patient. Mr. MARTIN said that he invariably used morphine in acute peritonitis and was convinced that it was life-saving. He had used it both in traumatic cases during the war and in ordinary cases following appendicitis and perforated ulcer, as it prevented distension and brought about rest. Mr. DONALD asked whether Prof. Morley would differentiate between children and adults in the matter of drainage, remembering the old adage: "When in doubt with an adult, do not drain; when in doubt with a child drain." Mr. SOLLY COHEN asked whether there was any danger in giving blood rather than plasma. Was the increased cell concentration dangerous? He wanted a reasonable explanation of what was meant by peripheral circulatory failure. Again, what penicillin dosage should be given? Which type of sulphonamide was most useful given by mouth? What was meant by the term "splanchnic reflex"? He doubted whether the Fowler position itself contributed to subphrenic abscess.

Mr. Rob, in reply, said that during the war he had treated abdominal wounds both before and after the introduction of penicillin. Of 89 abdominal wound cases treated with sulphadiazine, none of which were drained, the abdominal incision became infected in 6. Of 37 treated with sulphadiazine and penicillin, all healed by first intention. On the question of blood or plasma, in his opinion blood should be used when blood had been lost and plasma when plasma had been lost as the two fluids were not interchangeable. Prof. MORLEY said he was sure that for peptic ulcer drainage was not only unnecessary but dangerous, because it was so particularly liable to give rise to bands of adhesions. He did not attach much significance in acute cases to the blood picture. One had to depend much more on the general clinical phenomena. He was a whole-hearted believer in the use of morphine in peritonitis; the bowel needed the rest which morphine ensured.

FAMILY PLANNING ASSOCIATION

Some 130 doctors attended a medical conference of the association held on Nov. 24, when "the experience of some local authorities in providing contraceptive advice within the term of the Ministry of Health Memoranda" was discussed under the chairmanship of Dr. ANNIS GILLIE. Since 1933, thanks largely to the F.P.A., the provision of advice on contraception at clinics has become a generally accepted part of the medical services, and there was great hope of further progress under the new Health Act.

Dr. MARGARET TURNER described her experiences in running one of the ten clinics provided by Essex County Council and emphasized the great need for a service which would cover fully all the aspects of family planning, such as marriage guidance, sub-fertility, and the treatment of minor gynaecological ailments as well as contraception. Experience in many different types of clinics was represented in the ensuing discussion, which ranged widely over all the problems that their organization present.

Developments in the Treatment of Sub-Fertility

With Prof. W. C. W. NIXON in the chair, Dr. MARGARET JACKSON outlined the methods and investigations that she used and made the following points: that one of the most important aspects of the clinic was to sort out the hopeless from the hopeful patients; the importance to the peace of mind of the former group of patients of knowing exactly where they stood could not be overestimated; that as fertility was greater before than after the age of 30, it was important for married couples to try to have children as early as possible so that if sub-fertile they should have a chance of successful treatment. She emphasized the importance of investigating the husband as well as the wife and illustrated the growth of her work by the fact that, whereas in 1933 0.5% of her clinic patients came for sub-fertility, the proportion is now 33%.

The conference ended with a showing of the film "Studies in Human Fertility," which was made in the United States and has been used in that country for the instruction of medical students.

SURQUALET THE NEW ELECTRIC STERILIZER

Makes the
Sterilization and
Assembly of
Syringes

Safe, Easy and Foolproof.

- Operates on Universal Voltage of 200/250 volts A.C. or D.C.
- 6 ft. of Cable provided with Universal Plug for Bayonet or 2-pin Sockets.
- Capacity 1 pint . . . boils in 10 minutes.
- Specially designed Lid keeps all Condensation inside Sterilizer.
- Heat Resisting Plastic Jacket keeps Cool during Use.

Price : £5 15s. 0d. each

Doctors are invited to examine this new gauze-covered sanitary tampon

Distribution of Lil-lets sanitary tampons is increasing. As every carton states that the unmarried woman and the young girl should only use tampons if recommended to do so by her doctor, increased requests for advice may be expected. Doctors are invited to examine the construction, size, finish, and packing of Lil-lets. An uncompressed specimen, together with the carton of one dozen as sold commercially, will be sent on receipt of professional card.

Lil-lets are sanitary towels, made of highly absorbent cotton wool, compressed to small tampon shape. Each one is wholly contained in fine absorbent gauze; this eliminates risk of disintegration. The tampons are coated with a thin, instantly soluble, and innocuous film which ensures easy insertion without the use of an applicator.

Receipt of professional card without other enclosure will be taken as permission to send the specimens.

The Successful Treatment of FIBROSITIS and certain cases of RHEUMATISM with NOVUTOX

A mass of evidence has accumulated to show that the treatment of Fibrositis and certain cases of Rheumatism with Novutox injections provides not only complete restoration of function with immediate relief from pain, but also, in many cases, early recovery.

Interested members of the medical profession are invited to write for a copy of a Thesis on "THE INJECTION TREATMENT OF FIBROSITIS—with special reference to: Lumbago, Muscular Rheumatism (Acute and Chronic), Muscular Pain (of Traumatic Origin)."

NOVUTOX is available in:

2-oz. and 20-oz. Bottles: $\frac{1}{2}$ %, 1% and 2% Solutions.

Boxes of 12 x 2 c.c. Ampoules: 1% and 2% Solutions.

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.00002 gm. epinephrine and 0.00002 gm. capryl hydrocupreinoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

(ASCORBIC ACID B.P.)

It is generally accepted that vitamin C intakes appreciably greater than those required to prevent the appearance of prescorbutic states have a marked beneficial effect on general well-being; consequently the provision of a generous extra dietary source of vitamin C is advocated before surgical operations and during convalescence from these and from infective diseases.

Collateral administration of vitamin C with metallic compounds and chemotherapeutic substances is also recommended to mitigate toxic effects and augment therapeutic efficacy. Further information is available on request.

A SUMMARY OF THE ADVANTAGES OF STREPH

- (1) Non-selective.
- (2) Activity is maintained in the presence of proteins.
- (3) Non-necrotic, non-toxic, non-staining.
- (4) Clear solutions with water, normal saline, and alcohol.
- (5) Powerful deodorant.
- (6) Almost odourless.
- (7) Powerful detergent and compatible with soap.
- (8) STREPH is approximately three times as effective as Liq. Chloroxymolis or lysol.

For these reasons STREPH is the ideal antiseptic for medical, surgical, and obstetrical use.

Literature and sample on application to
JEYES' LABORATORIES LIMITED,
LONDON, E.13

Amethocaine hydrochloride is the choice of an increasing number of anaesthetists for regional anaesthesia. It yields a high degree of muscular relaxation combined with minimum operative and post-operative shock.

Regional "D" (Duncan) is supplied in sterile glass ampoules and consists of dry amethocaine hydrochloride which should be dissolved in sterile normal saline before use. It is indicated for abdominal field block, brachial plexus block, epidural block, etc. It may be used with the same confidence as is placed by the medical profession in the other world-famous Duncan, Flockhart anaesthetics.

Regional "D" (Duncan) is available in two strengths in ampoules containing 100 mgm. and 300 mgm. of amethocaine hydrochloride.

Unswerving Support

SIR,—I resigned from the B.M.A. at the end of 1939 owing to a difference of opinion with an official of the Association on what I considered a matter of principle. For the past three months I have been reading the *Journal*, and am now quite convinced that not only is this not the time to perpetuate a grievance (fancied or otherwise), but that it is the proper time for every member of the profession who values his personal liberty and the welfare of his patients to give his unswerving support to the Association. I am therefore making a formal application to the Association to be readmitted to membership to-day.—I am, etc.,

London, N.19.

C. H. JOHNSON.

The Plebiscite

SIR,—I have answered "No," but I am distressed to think that my answer may be construed as having the implications referred to in the preamble of the plebiscite form. I hold that "the profession should decline to accept service under the Government scheme," but I do *not* hold this opinion "in view of the wide divergence between the principles of the profession and the provisions of the Act," for I disagree with the first four of the five decisions of the Representative Body mentioned in Dr. Hill's letter.

I approve in principle of the enactments regarding "direction," State ownership of hospitals (but not nursing homes), sale of practices, and basic salary; but my emphatic hostility is aroused by the many points—I have counted eighteen in the Act—at which the Minister may exercise an arbitrary power. To my mind the worst of these eighteen relate to his (a) withholding the annual report of the Central Health Services Council, and (b) compulsorily acquiring any medical institution which may be set up in the future. If the referendum shows a substantial majority of "Noes" I trust that the Council will not aim that this majority is unanimous in its reasons for condemning the National Health Service Act.—I am, etc.,

London, N.19.

G. A. VAN SOMEREN.

SIR,—To read the correspondence in recent numbers of the *Journal* one might think that the future of the human race was at stake in the plebiscite. Your correspondents dislike the Labour Government and all that it stands for. Let them say so and have done with it but not confuse the issue by indulging in political diatribes. The fact is that the Labour Government (supported in this instance by the Liberal Party) have a clear mandate from the electorate to pass the National Health Service Act. Your correspondents forget too that all political parties and the B.M.A. have urged the creation of a free and comprehensive health service. In 1944 the plebiscite of the medical profession confirmed this general wish, and more recently the students have shown that they were largely in favour too.

We doctors now have the right to negotiate with the Minister regarding the terms of service. Shall we now behave like a lot of sulky schoolboys and refuse to have anything to do with an Act of Parliament which clearly represents the wishes of the country? One's only possible doubt in answering "Yes" is whether we are wise in putting the powers of negotiation in the hands of men who have already shown their political bias and determination not to meet the Minister in a reasonable spirit.

Is the Negotiating Committee a democratically constituted body? What say—direct or indirect—had the Service doctors? Can it or the Council of the B.M.A. be said to represent the wishes of the majority of the profession? There must be tens of thousands of members of the B.M.A. who have joined—this being the cheapest and most convenient way of securing the *Journal*—and who never attend B.M.A. meetings. The difference between the viewpoint of the B.M.A. Council and the Negotiating Committee on the one hand and that of the profession as shown by the 1944 plebiscite on the other is so marked that one is forced to conclude that the former do not really represent the opinions of the profession as a whole.—I am, etc.,

H. B. O. CARDEW.

Bristol.

Northern Ireland and the Plebiscite

SIR,—Dr. Conn McCluskey's letter (Nov. 23, p. 791) came under discussion at a Divisional committee meeting this afternoon. I am asked to take immediate steps to correct the impression which may be given. The committee has no reason to assume that Mr. Grant intends to do anything other than follow the English Act in all its major details. It should not be assumed that the alternative measures which Dr. McCluskey mentions will be acceptable to the Northern Ireland Government. All evidence points to the opinion that Mr. Grant will be compelled to follow the English Act closely. Northern Ireland practitioners should not permit themselves to be misled by any assumptions to the contrary.—I am, etc.,

Belfast.

DOUGLAS BOYD,
Hon. Secretary, Belfast Division,
British Medical Association.

The Act and Ophthalmic Treatment

SIR,—Those of us who have interested ourselves in this National Health Service during the past four or five years are amazed at the apathy of the medical profession generally in a measure like a State Medical Service, which affects their living and their mode of life. Most Divisions have held meetings to discuss this plebiscite; and I should think that the experience of other Divisions has been much the same as our own at Guildford, where 12% came to hear the views of their colleagues on this subject. Of those who came the vote was a unanimous "No," and I take it that if there had been any very keen "Yes"-men they would have come to the meeting to state their views.

The planners are already at work, and in ophthalmology major ophthalmic surgery is only to be performed at key hospitals. Smaller hospitals which may have quite considerable ophthalmic departments are to be closed, for major surgery at any rate, for no better reason than that they are small hospitals. The key hospitals are well named, for those who are already installed in what are to be the key hospitals not only have the key of their own hospitals but also intend to take the key of hospitals with which they have had previously no association, and lock the door at will. I fully realize that it is only by closing the smaller hospitals that patients could be compelled to make the long journeys to key hospitals which they have been unwilling to make in the past.

Surely this must be the writing on the wall for the whole profession; and it is quite incredible to me that doctors who may have been 20 or 30 years in practices of their own should now be willing to return to their house-surgeon days without so much as a fight.—I am, etc.,

Camberley.

LESLIE HARTLEY.

The Patient's Dilemma

SIR,—Apropos the National Health Service Act, wherein we are assured that the mutual freedom of choice as between doctor and patient will be retained, how would one reconcile the fact that when a practitioner chooses to remain and practise outside the scheme his patients will not be provided with free medicines and appliances under the Act. Yet, it is presumed, these same patients will compulsorily have to pay their weekly contributions to that scheme without deriving any medical benefit from it.

Should they insist upon their rights to free medical benefits under the scheme they will presumably be advised or directed to join the list of a practitioner within the scheme. Is this consistent with the freedom of choice of a doctor by the patient?—I am, etc.,

Aldershot.

D. M. RAYNES.

National Health Service Act

SIR,—Surely no right-minded citizen, no matter what his political views—unless Fascist—could desire the B.M.A. to negotiate terms with the Minister of Health. The Act as it stands is an unscrupulous, expensive political pawn which gives the Minister dictatorial powers over the medical profession. The Socialist should bear in mind that the next Minister of Health might be a Conservative.

The expense of running this dictatorship, with its multitudinous subcommittees and boards, all ultimately appointed by the Minister, does not bear thinking.

which is on the borderline of bankruptcy it is not ludicrous but terrifying. Those prepared to use the Act as a basis of negotiation admit by implication approval of it as far as it goes. It is not a case of making the best of a bad job, but of resisting evil all along the line and having as little to do with it as possible. The idea of increasing the facilities for, and the medical care of, the country is good and perhaps overdue; but we must not be party to a scheme which can only lead to a decrease in this ideal.

A further rather important snag in the scheme as proposed, which seems to have been overlooked at the present, is in regard to hospital accommodation. The latter is inadequate at the moment to cope with all the cases who would honestly benefit from it. In consequence many patients are treated as well as possible, and frequently with success, in their own homes, though ideally they would be hospitalized. Under the new scheme all pay equally to the upkeep and have equal right to the very best care. Therefore all these cases have the right to hospital treatment. What right has the mere doctor, an executive in a monster machine, to deter them merely because the bed situation is difficult? At the moment, because it is not a "right" for all, the doctor can and does use his discretion, even though this may throw a great deal of hard work upon him—visiting regularly the more seriously ill. The situation might become, and certainly could be made, quite impossible. —I am, etc.,

Cheam.

NEVILLE K. CONNOLLY.

SIR,—A decision not to enter the National Health Service would be, according to your leading article of Nov. 16 (p. 739), "strictly legal and honourable" (italics mine). I entirely disagree.

The "fundamental principles" on which the B.M.A. has taken its stand are not moral principles. They are merely political, the cornerstones, in fact, of Conservative policy—private enterprise (or practice); private ownership (of practices); vital businesses (including medical practices) run as independent, competing, profit-making units, unplanned as to their location or number; and minimal "evolutionary" changes at slow tempo. But these are no longer the guiding principles of society. A Socialist administration has been freely elected to power and is committed to the nationalization of certain basic undertakings—communications (Cable and Wireless, Ltd.), banking, coal-mining, railways, and medical services.

We are entitled no doubt to vent our displeasure and disappointment to a reasonable extent, but do not let us carry opposition too far. We are citizens even before we are doctors, and we have surely a moral obligation as citizens to co-operate in putting into effect Acts passed by Parliament however distasteful to us personally. I suggest our profession should take its "medicine" in a sporting spirit and try to make a success of the National Health Service. This is probably, moreover, wise practical politics. In the event of a prolonged and bitter struggle with the Government it is we, I am convinced, who would suffer most.—I am, etc.,

Wallasey

LENNOX JOHNSTON.

SIR.—A useful purpose may now be served to forecast the present views and feelings of medical men as judged by the literature, personal contacts, local meetings, and consultant gatherings in London. As I see the position, individual opinions may be grouped into four classes.

1. Against any clause or remote threat which involves loss or possible loss of freedom. A majority, I am sure, if they are honest hold this view, but not all of them will commit themselves. A large backing of unshakable, determined men and women is essential in this category, not only to prevent the dangers of shackles, dictates, and direction, but as an example to the next group.

2. A weak collection of waverers who need guidance, further knowledge of the dangers threatening, and an assurance of their personal safety; some of these individuals are continually wondering what their colleagues in opposition practice will do instead of making up their own minds and helping the team.

3. Those who favour undiluted State service. Included here, of course, are the small Socialist group. Many of these doctors are young, have been in the Services, or may still be serving. A large number of these have seen the red light on returning home and discussing matters with colleagues, or having listened to addresses. Such men and women, fearing for their future livelihood, should be made to realize that there is a shortage of doctors and room for all

in our country. Apparent Government concern for their poverty is just propaganda.

4. A necessarily small group of leaders and those in high places, whose recent expressed views are, to put it mildly, disturbing. This is a pity, as many would have liked a strong lead from such presumably well-informed quarters. This is no time for half-way measures and compromise. It does not seem possible that such people are willing to take a risk and give way on some of the principles agreed by a great majority of the rank and file. This vacillation from a position mid-way between the Government and the main loyal body of the profession is not good enough. It should be realized such is in fact the case—hence the dangers of saying "Yes" in the referendum. After the way in which the Bill has been introduced, a Bevan concoction, without advice from those expected to work it, refusal to discuss matters, a *fait accompli*, etc., surely such matters can be met only by standing firm on any point even remotely threatening future dictation. Let us hope that these important individuals, on account of their high level, will not fear to present a bolder front when the time comes.

I believe our position generally has been greatly strengthened of recent months. We hope that the quiet, unassuming Guy Dain and others will not cease their valuable addresses to groups of medical men. If they need any encouragement they might like to know that they have made many converts and assisted others to a firmer frame of mind. It may help some to know that at a recent discussion of Fellows it was obvious that the rank and file of consultants and specialists present were, as far as I could assess, wholly or almost entirely in favour of supporting the principles already laid down. I mention this because there is a growing feeling among general practitioners, whose house is now in better order, that the profession may be let down by the consultant or specialist. Meetings at the Royal College of Surgeons do not appear to support this view. Mr. Reginald Payne, Laurence Abel, and others should be thanked for their efforts at the Fellows' discussion. Mr. Payne, who has taken much trouble in studying laws, rules, and regulations, and the dangerous growing power of the politician, should receive special thanks for his effort, and I hope he will publish his remarks. During his lengthy and necessarily dry discourse I heard a whisper behind me, "For Heaven's sake keep politics out of this discussion." Such a remark savours of much dangerous ignorance. Much as we dislike it the politics of the present Government are thrust on us and we must face, discuss, and fight the dangers inside and outside the profession.

How many doctors know the meaning and implications of the "closed shop"? Why must we wait for incidents like the Willesden Hospital staff-sacking threat before we blink our large baby blue eyes! It will be amusing to see how the Ministry of Health explain or minimize this blunder. Possibly to save face some minor official will be rapped over the knuckles. The "closed shop" is on our doorstep. Basic freedoms and minorities are daily involved in an overbearing and destructive process. The medical profession is a minority community, unassailable if we stand together. We have the opportunity; we have also a chance of perhaps setting an example and encouraging other bodies of men and women who are British to call a halt to the Britons already on the road to serfdom. We do not seem to realize the dangers, in spite of having just emerged from the world's greatest disaster—the result of a one-party dictatorship.

I cannot understand how supposedly sane professional men and women can countenance drastic changes and chances at this particular moment of all moments in our long and honoured medical history, while the process of aping recent Continental dictatorships is in our midst and hot-headed M.P.s will tell us when, where, and how we will do our work. I recommend this thought to everybody—even to those who would fail us in the fight for freedom.—I am, etc.,

Torquay.

W. ETHERINGTON-WILSON.

Ends and Means

SIR.—I have just received a copy of Bulletin No. 16 from the Medical Policy Association (London), which strongly urges the professions not to send a deputation to the Minister of Health to discuss with him the Health Act. I am second to none in my dislike of the Act, and the overbearing attitude of the Minister in the matter. I deplore the proposed rape of the hospitals and the twilight of the freedom of medical men as

individuals. Nevertheless, in my humble opinion a refusal to meet the Minister is playing right into his hands—it is both undignified and unwise. One can almost hear his reply—"I have them a chance to meet me, and they sulked and would not play." It would show a pettiness that is unworthy of the profession. I believe a large section of the public would take the same view, and we cannot afford to ignore public opinion in such a vital issue.

The last paragraph but three (heavy type) leaves one bewildered, if words have any meaning. It states: "To vote or negotiation is to agree with the Minister's aims because *you cannot honestly discuss means unless you are in agreement with the ends.*" One assumes that the deputation would tell the Minister in unmistakable terms what it thinks of the Act as a whole—and of many of its clauses. How this could be construed as "agreement" passes comprehension.—I am, etc.,

London, N.20.

B. HALLEY STEWART.

Cerebral Malaria in Britain

SIR,—I read with interest the account (Nov. 30, p. 815) by Drs. J. R. Ryder and R. T. Towson of their case of cerebral malaria, which reminded me of a case seen by myself and described in the *Journal* of April 27 (p. 650). In my case the patient was completely comatose and had not had any previous recognized attack of malaria, but he did show a profound amoebolytic anaemia and an enlarged spleen.

As in the case of Drs. Ryder and Towson, my patient had not long returned from W. Africa, and the onset of coma and high fever in a young man from that region roused an immediate suspicion of the presence of cerebral malaria. His condition appeared so desperate that an even larger dose of intravenous quinine (20 gr.) than that given by Drs. Ryder and Towson was employed. He made an immediate recovery, but my impression was that had effective treatment been long delayed this would not have been the case.

I reiterate these facts to support the statements in the recent case report that cerebral malaria should be considered as a possible cause of coma and that its early treatment is essential. The fact that a febrile comatose individual has not long returned from an area where malignant tertian malaria is endemic should certainly make us alert to this possibility.—I am, etc.,

Edgware,

G. H. JENNINGS.

Evaluation of Barrier Creams

SIR,—I would like to pay tribute to the article by Drs. G. A. Sadler and R. H. Marriott (Nov. 23, p. 769) and to their caution in presenting their conclusions. The practical use of barriers (and I think the writers would agree) is bound up with the physical and chemical factors operating in the aetiology of industrial dermatitis. One of the most neglected aetiological factors is that of friction. Often enough the causation of industrial dermatitis is not merely that of skin plus irritant, but of skin plus irritant plus friction. The element of friction is so important that certain abrasives, chemically inert, can by virtue of their physical property alone produce an eczematoid reaction. With substances chemically hostile to the skin the sites of the rash are not necessarily those places where the agent soils the skin: it is more often those soiled areas where the agent is rubbed into the skin. So a man whose whole forearms are bathed in irritant may only present a rash where his rolled up and soiled shirt sleeves constantly abrade his skin, or where the ulnar borders of the forearm rub against a protective apron or on a bench.

Because of this element of friction medical officers in industry must often be struck by the exact similarity from case to case where these dermatitis cases come from one particular job. The importance of this element of friction can be readily understood by computing how many thousands of times a muscular movement may have to be performed in a day's work. By virtue of this repetition a mildly irritating substance may be transformed into a potent source of dermatitis. All this is important in regard to the practical use of barrier creams for very obvious reasons, and because of these reasons it is not uncommon to see a correct barrier religiously applied proving useless.

Nevertheless, friction should not be overstressed. Dermatitis occurs where this is minimal, as in the formalin dermatitis of laboratory workers; but in this sort of case the chemical is often potent and hostile to the skin to an unusual degree. Where friction is great, chemical irritation can be minimal, but where friction is slight, chemical potency must be marked in order that a serious cause of dermatitis may arise. No doubt this is only a rough rule to which there are exceptions, but it may well be that a motion study of employees at work, with a view to minimizing wear on the skin, could often be a better answer than the application of a barrier to the skin. It is at any rate remarkable in industry that the risk of dermatitis does not necessarily run parallel with the irritating power of the substances handled. The very irritant substance may in practice be less harmful than a mild chemical because the nature of the work may be the main determinant.

The housewife might merely immerse her hands in warm alkaline solutions with impunity, but who can doubt that the element of friction on washing-day adds the final touch to the destructive power of the alkali on the horny layer? How does a barrier behave to this great but unrecognized element of friction? It seems to me an important point in very many jobs with a dermatitis risk.—I am, etc.,

G. WHITWELL.

Penicillin and Acute Puerperal Mastitis

SIR,—Drs. Mary Taylor and Stanley Way's instructive publication on "Penicillin in Treatment of Acute Puerperal Mastitis" (Nov. 16, p. 731) has appeared most opportunely for me, as I have just finished my observations on a case of mine.

CASE REPORT

A.B., aged 34 years, para. 2. On Oct. 23, 1946, dribbling of liquor amnii commenced, and continued with irregular short pains. Admitted into the maternity home late Oct. 27. Occipito-posterior position of the vertex, with restitution and abrupt normal termination of a tedious labour on the evening of Oct. 28. Lactation commenced Oct. 30.

Nipples cracked and breasts began to be tender on Nov. 1. Rigor and pyrexia 102° F. (38.9° C.) early hours of Nov. 3. By mid-day temperature was normal and breasts soft with no tenderness on pressure. Lactation stopped. Nov. 7: rigor and pyrexia, with flushing and exquisite tenderness of the left breast and lower half of the right breast. The patient felt and looked ill. Penicillin injections commenced Nov. 8—500,000 units twice daily till 5,000,000 units had been injected. Nov. 11: patient passed from great distress into comfort, and the breasts became soft and palpable.

Nov. 13: patient returned home and is now going about. Stilboestrol 5 mg. was administered throughout this treatment, and breasts were pumped.

The magical clearing up of both the breasts under the massive penicillin injections in so short a time is worthy of note.—I am, etc.,

Warrington.

FEROZE GANDEL.

"Benadryl" for Penicillin Urticaria

SIR,—The article by Lieut.-Col. R. R. Willcox (Nov. 16, p. 732) on the use of "benadryl" for penicillin urticaria prompts me to record a recent case in our practice in whom a similar beneficial effect has been observed in urticaria following liver injections.

This is a woman who had been having a maintenance dose of 2 ml. "anahaemin" monthly for the past five years for pernicious anaemia. In January this year she had a mild urticaria following her injection, which settled down after a few days. After her next injection in February she had a most violent and profuse attack of urticaria with oedema of the tongue, the glottis, and the eyelids—this despite the fact that 5 min. (0.3 ml.) of adrenaline was given with the "anahaemin." Once more "anahaemin" was injected with 10 min. adrenaline, but with the same unfortunate effect. After this she refused to have any more. An attempt was made to desensitize her by giving her orally minute increasing doses of proteolysed liver, but each time she reached about a teaspoonful dose the urticaria appeared again.

On Oct. 16 I was summoned to see her and found her in a state of collapse, with dyspnoea, feeble heart sounds with tachycardia, and oedema of the feet and legs. Her pallor was intense,

and she was almost moribund. From that date onwards for a fortnight she was given 2 ml. "anahaemin" daily, but at the same time she took two capsules of "benadryl," 50 mg. each t.d.s., and to my great relief and hers no urticaria appeared. For the past three weeks she has been given 2 ml. "anahaemin" twice weekly, and the dose of "benadryl" has been reduced gradually to one capsule taken after the injection only. As an experiment, on two occasions the "anahaemin" has been given without "benadryl" at all, and each time a mild urticaria of the arms and legs has appeared.

She is now very fit, and is continuing on once-weekly injections of the liver followed by one capsule "benadryl," with no untoward effects. No haematological examinations have been done on this occasion, partly for financial reasons and chiefly because the diagnosis of pernicious anaemia had been established in the past.—I am, etc.,

Bournemouth.

JAMES NICHOLSON.

Treatment of Osteoarthritis by Lactic Acid Injection

SIR,—I am grateful to Dr. R. Mawson for his article (Nov. 9, p. 691), and I envy him his power of lucid exposition and graphic description. As originator of this method of treatment I find little to cavil at, and if I differ from him in certain details of technique I hope he will not think me captious. During the last twelve years I have been responsible for the injection of approximately 10,000 cases, and this experience has led me to the following conclusions.

(1) It is a mistake to use a local anaesthetic. I use much finer needles than Dr. Mawson—e.g., for hip-joint a needle $3\frac{1}{2}$ in. (9.4 cm.) with a bore of 0.55 mm., for the knee a needle of 20 S.W.G. bore. (Incidentally, why, oh why do the manufacturers cut down the length of the needle with the bore?) I attribute my complete absence of sepsis to these two factors.

(2) I very rarely use the anterior approach to the hip-joint, for the reason that effusion in the joint (more often experienced than I had thought likely) or an excessive amount of periarthritic thickening may displace the vascular packet and the femoral nerve laterally, and in stout patients the pulsation of the artery is not easily felt.

(3) For the wrist-joint proper I inject via the anatomical snuff-box; but the division of this joint into radio-carpal and ulna-triangular ligament-lunate articulations is an artificial discrimination remote from clinical reality—vide Prof. Seddon's x-ray movies of the wrist or the average case of atrophic arthritis, where the ulnar side of the wrist is frequently more seriously affected than the radial; and I agree with Dr. Mawson that it is frequently useful to enter the wrist-joint via the ulnar side. In any case the synovial cavity communicates on the proximal side of the triangular ligament with the inferior radio-ulnar joint, and on the distal side with the radio-carpal articulation.

(4) I believe from x-ray examination that if severe pain is complained of immediately after injection the point of the needle is under the periosteum or the cartilage. I have not experienced it since I formed the practice of withdrawing the needle a short distance before pushing the plunger. Deliberate infiltration of the thickened capsule does not cause undue pain.

(5) The use of acid injection in active atrophic arthritis is not recommended. My admittedly inadequate observations of the joint pH in this phase tend to show that it is certainly not alkaline.

The suggestion has been made repeatedly that the procaine is the active ingredient in the improvement gained: Warren Cowie, however, using acid potassium phosphate without procaine, obtained highly satisfactory results; and in any case, most procaine solutions have a pH figure well under 7.—I am, etc.,

Sunderland.

W. GRANT WAUGH.

Immunization against Whooping-cough

SIR.—It is very encouraging to read in the *Journal* of Nov. 9 (p. 699) that the Medical Research Council is initiating in certain limited areas, in co-operation with the medical officer of health of those particular areas, experimental inoculation against whooping-cough. Its results and conclusions will be awaited with great interest.

The following comments are from the point of view of G.P. interested in this subject for close on 20 years. (Sugar H., and McLeod, J. W., *Lancet*, 1929, 2, 165.) There is great need in this country for a more extensive study of immunization against this disease, which causes such impairment of health and loss of school attendance. Several extensive investigations of its value have now been carried out, chiefly in Denmark and the United States. Their results are very favourable as to its successful prophylactic use.

It is suggested that facilities for active immunization against whooping-cough should be made available by the public health authorities in the same way as in diphtheria, taking into account the view that the injections should commence about the age of 6 months. Combining the injections against whooping-cough with those against diphtheria has also been used. Preliminary trials have been favourable in doses of 0.5 and 1 ml. at intervals of four weeks. This combined vaccine is not generally available. More extensive trial is required, however, before assessment of the efficacy of its prophylactic use can be established.—I am, etc.,

Leeds.

H. SUGARÉ.

The Fenestration Operation for Otosclerosis

SIR.—In the interesting article by Mr. I. Simson Hall (Nov. p. 647), the passive part attributed to the stapes, one of the most fascinating mechanisms in the body, appears to me rather misleading:

In 1931 I challenged the theory, held at that time, that the function of the secondary membrane was limited to permitting the passage along the *scala* of movements generated at the *fenestra ovalis*, and I give a brief summary of the main points in support of my present view. In the case of a cone, such as that of the *membrana tympani*, with its base attached to the *sulcus tympanicus* and its apex directed inwards, any movement inwards would be arrested, and its pressure sustained by its attachment to the *sulcus*. The pressure of the apex of the cone and the resulting movement of the *malleus* would represent a negligible fraction of the energy of a sound wave. I maintained that, mathematically, pressure on the interior of a cone of radiating fibres would produce movement of the apex inwards, towards and not away from the base.

Subsequently, in my little work *Hearing and Equilibrium*, published photographs of an improved model (Figs. 1 and 2) which, in my view, demonstrated conclusively that the hypothesis was correct, and that pressure, insufficient to produce extension of the fibres, tends to convert the cone into a segment of sphere, which expands as the pressure exceeds that strength. In the case of the *membrana tympani* the effect of the initial change is a movement of the apex and manubrium outwards towards the plane of the *sulcus*, while that of the second change is a movement in the reverse direction; movements respectively supplementing weak, and resisting excessive, movements of the fluid generated at the *fenestra rotunda*. The only light pressure which would resist, instead of assisting, the outward movement would be any directly on the handle of the *malleus*; but owing to the downward direction of the inner end of the external canal and the further extension downwards of its roof, wave sweep down towards the *fossula rotunda*, across rather than against the membrane, and the short process of the *malleus* diverts pressures, which would otherwise reach the handle, on to the membrane on either side. In the middle ear the depth, direction, and position of the *fossula ovalis* protects the surface of the stapes from pressures created by sound waves, while not interfering with the action of the ossicles. Finally the fluid movements generated by the secondary membrane are immediately to and from the *scala tympani*; while, on the contrary, those by the stapes are directed across the entrance to the *scala vestibuli*, a construction which, for reasons given elsewhere, does not affect its supplementary action.

Action of the *tensor tympani*.—Waves do not penetrate the *membrana tympani*; movements in the middle ear in harmony with sound waves are generated by its deep surface. Those from its lower more vertical part are directed immediately towards the *fossula rotunda*; while those from its upper relatively more horizontal part are mainly directed to the region above the *fossula ovalis*. The *tensor tympani*, responding to sound in a manner resembling the response of the iris to light. As sound becomes excessive it forces the stapes into the *fenestra ovalis* with

increasing strength, thus preventing excessive movement of the fluid. Simultaneously it raises the tension of the membrane, reduces the amplitude of the movements generated by sound waves and, consequently, of the movements generated by its deep surface towards the *fossula rotunda*. It would be difficult to conceive a more beautifully co-ordinated arrangement for the rapid appropriate conversion of a supplementary into a protective mechanism.

The apparatus consists of a cone of elastic tissue ribbed with comparatively inelastic material, and sealing the upper glass vessel, thus simulating the *membrana tympani* separating outer and middle ears. Two straws (B and S) lie side by side across the base of the cone, but S is hinged at H, and has a looped attachment at L to a small vertical straw resting on the apex of the cone, while A serves as a guide and an indicator for the upward movement of S. S thus simulates the *malleus*.

Fig. 1

Fig. 2

In Fig. 1 the atmospheric pressures are equal on the two sides of the membrane, while in Fig. 2 the glass chamber is partially evacuated with the cone assuming a more hemispherical shape and its apex unexpectedly rising as a consequence of the inelasticity of the radiating ribs.—I am, etc.,

H. MACNAUGHTON-JONES.

Facial Palsy Accompanying Acute Mastoiditis

SIR,—With regard to Mr. Arthur Miller's letter (Sept. 28, p. 474), it seems to be worth mentioning that high power magnification now enables one to view the horizontal or intratympanic portion of the facial canal much more clearly than before. The pinkish-yellow nerve appears to be very thinly covered by bone, so thin in fact that one suspects that an actual dehiscence is present, only to find that there is a covering of very transparent bone. Personally I am surprised that facial palsy is not more common when the tympanic cavity is the site of severe inflammatory changes.—I am, etc.,

London, W.1.

IAN G. ROBIN.

SIR,—May I comment upon the sulphonamide treatment of Case 4 of facial palsy accompanying acute mastoiditis as reported by Dr. Kenneth R. Ogilvie (Aug. 24, p. 263), as this is a matter of considerable importance. The history as reported gives no information as to the onset or duration of the preliminary attack; and apparently, although otorrhoea was present, the only treatment was "a sulphonamide—2 g. daily for five days."

It is a golden rule in cases of otorrhoea that the ear must be kept "clean and dry," and this suffices for the great majority of cases—at least in this part of the world. With regard to sulphonamide therapy, it is unfortunate that indiscriminate and ill-informed use of sulphonamides is so widespread. Sulphonamides are not without their dangers, but it must be realized that insufficient dosage is worse than useless, for not only does it fail to cure but it does develop resistance to sulphonamides in organisms that are otherwise susceptible, and may lead to a false sense of security. I consider it wrong and dangerous to give sulphonamides to ambulatory patients.

In the case in question 2 g. daily for five days was a totally inadequate dosage, and from the information given was probably administered not early enough. In cases of acute otitis media the administration of sulphonamides must be in adequate dosage, be commenced early, be conducted with the proper

safeguards, and under careful supervision. Neglect to observe these conditions has been responsible for much unwarranted criticism of the use of these drugs in acute otitis media. To reserve chemotherapy for "cases which show a tendency to spread outside the mastoid process . . ." is to subject many patients to the risk of operations, illness, and expense which could be avoided by early and sufficient intelligent care.—I am, etc.,

Brisbane.

ERNEST CULPIN.

Transmesenteric Hernia

SIR,—The recent correspondence on this relatively uncommon subject has produced interesting differences of opinion concerning its aetiology. As I recently had the opportunity of operating on one of these cases I would like to add my support to the view of its congenital origin so well stressed by Mr. E. G. Dolton (Nov. 2, p. 667).

In my case there was a history of apparently intermittent obstruction extending over a fortnight, and the patient when seen was in *extremis*. There had been no history of abdominal injury. At operation it proved impossible to reduce the prolapsed small gut, and as the obstructing twist was seen in the terminal two inches (5 cm.) of the ileum and was not gangrenous, a rapid lateral anastomosis between the lower portion of the distended ileum and the caecum was done. Unfortunately, on completion of the operation, a tragedy supervened. The patient vomited violently and aspirated a quantity of vomitus, dying in a few moments despite all attempts at aspiration and cardiac massage, etc. I should add that the stomach had been emptied and spinal analgesia employed, but it was found necessary to supplement this by inhalation anaesthesia.

At the subsequent necropsy it was found that the opening in the mesentery measured four inches (10 cm.) at its greatest diameter and was approximately circular. Twelve feet (3.6 m.) of small gut had herniated through the opening, explaining the difficulty in attempting to reduce it at operation. But the important point was that a very careful and detailed examination of the edges of the opening was possible, and this left no doubt whatever that it was in fact a congenital development. Blood vessels of normal size ran along the free margin and anastomosed to complete the pattern before entering the gut. There was no evidence of any previous inflammatory changes and no evidence of healed blood vessels, which must have been torn if the defect had been caused by injury. The very shape of the defect—almost circular—must, I think, dispose of the possibility of trauma, since massive haemorrhage must have resulted.—I am, etc.,

Londonderry.

W. V. BEACH.

Fewer Strengths of Insulin Preparations

SIR,—Originally there was only one strength of insulin solution—20 units per ml. Now there are three strengths on our market—20, 40, and 80 units per ml. Each batch has to be carefully and expensively standardized, checked, labelled, and issued. The manufacturers and the M.R.C. carry out this long-accepted labour ingrained by pharmacopoeial regulations, and it remains for a clinician to state that it would be both helpful in practice and economical in production to omit the weakest solution—20 units per ml.

For many years my diabetic clinic and many others have never used the weakest solution—U.20—nor found it necessary. Even if an unusually small injection of under 10 units is being given, it can be measured accurately enough in U.40 strength. In doses of over 10 units U.40 should always be used for the benefit of small-bulk injections. For the same reason, for still larger doses U.80 should be used instead of U.40.

Mistakes in insulin dosage are all too frequent and would be minimized with only two strengths. Other countries have been worse off, and the Americans have produced 10, 20, 40, 80, and 100 units per ml. strengths. They now propose only two—40 and 80 units per ml. Surely there will be unanimity over this simple suggestion. The clinicians give their blessing, the M.R.C. and the *Pharmacopoeia* add theirs and change the regulations, the manufacturers bless everybody and act quickly—I hope.—I am, etc.,

King's College Hospital, S.E.5.

R. D. LAWRENCE.

Obituary

J. SHAW BOLTON, M.D., F.R.C.P.

After a long illness Dr. Joseph Shaw Bolton died on Nov. 12 at his home at Beaconsfield. He was born in 1867, son of the late Isaac Bolton, of Whitby, and elder brother of Dr. Charles Bolton, F.R.S. He was educated at Spring Hill School, Whitby, close to which his home was, and went on to University College, London, and to the medical school of University College Hospital. He took the degrees of B.Sc. in 1888, and of D.Sc. in 1912. In 1894 he qualified as M.B., B.S.Lond., with a gold medal in medicine, and proceeded to M.D. the following year. He became M.R.C.P. in 1902 and F.R.C.P. in 1909—to the latter distinction he was admitted on the same day as his brother, which one would suppose must surely be a unique event. He also received an honorary D.Sc. from Leeds University in 1934. At University College he was Atchison Scholar, Filler Exhibitioner, and Fellow of the College. After qualifying he was demonstrator of anatomy at his own hospital, and lecturer on physiology at Mason's College, Birmingham, in 1897-9. He was then appointed assistant medical officer and pathologist to the L.C.C. asylum at Claybury, and remained in the mental hospital services for the rest of his career. He was at Hellingly 1903-5, at Rainhill 1905-10, and was then appointed superintendent at Wakefield, where he remained until his retirement in 1933. He was also professor of mental diseases at Leeds University from 1911 to 1934.

Shaw Bolton was a tireless worker and a prolific writer, whose reputation was firmly established by his publication (in 1914) of *The Brain in Health and Disease*; he had then already to his credit the Goulstonian Lecture for 1910 on "Localization of Cerebral Function," and in 1935 he was Lumleian Lecturer to the College of Physicians on "The Evolution of Mind." He was also Maudsley lecturer in 1925, Henderson Trust lecturer in 1933, and author of monographs in Quain's *Dictionary of Medicine*. He was on the Council of the R.C.P. 1928-30, and President of the Royal Medico-Psychological Association in 1928. Such a record speaks for itself; and if he was not in sympathy with some of the more extravagant psychiatric speculations, it is yet to be proved that he was wrong. Even when immersed in the administrative duties of a very large mental hospital he found time to continue his pathological work, in which his researches were of real value. At the same time he had the gift of training his staff and of imbuing them with his own enthusiasm; many of his junior medical officers have subsequently risen to eminence in psychiatry. In 1906 Shaw Bolton married Miss Ellen Rogers, who survives him with their three children, two of whom—their daughter Marjorie and their son Reginald—are also members of the medical profession.

An old colleague writes:

His home life was a perfect example of domestic harmony and delightful simplicity, and to be a guest at his house was a most enjoyable experience. Content for himself with very simple fare, he encouraged without stint or limit the most gay and liberal hospitality, and although himself an abstainer he took pride and pleasure in the care of an excellent wine-cellar for the entertainment of his many friends. To know him well was to love him, and to some of his personal admirers it seemed sometimes unfortunate that the quite extraordinary charm of his personality was, by his retiring habits, concealed from the world that knew him only through his scientific work. He scorned to display this work with an eye to kudos or reward; and generously allowed those working under his direction to take full credit for research that would have been impossible without his guidance. Otherwise he might have attained even higher honours than he received. To his pupils and assistants he was a wonderful man, to whom they owed an irredeemable debt. In his home, to his own family, he was nothing more nor less than just Dad.—J. I. R.

WILLOUGHBY HENWOOD HARVEY, M.A.Cantab., M.D.Toronto, who died on Oct. 7, was a well-known figure in Cambridge. Born in Canada in 1881, he had several medical ancestors, some of whom practised in the backwoods of Ontario in early days. Harvey came to England and studied at Bart's in the first decade of the century, graduated M.B. at the University of Toronto in 1904, and subsequently entered Christ's College, Cambridge, as a research student in pathology, acquiring his M.A. degree by research. He held in succession almost all the research scholarships available, first a B.M.A. Scholarship and then the Beit, Grocers Company's, and John Lucas Walker Fellowships. During this time his work was mostly histological in connexion with arteriosclerosis, and he published in Virchow's Archives on experimental bone formation in blood vessels. For some years he worked with the late Prof. W. E. Dixon in pharmacology, demonstrating that excessive tea and coffee produced nephritis in rabbits; at one time he was excited to discover muscle in the kidney, only to find that it had been demonstrated long since and never got into the textbooks. In the war of 1914-18 he was captain, R.A.M.C., in charge of a central V.D. laboratory in Cambridge, and was later a Secretary of that Section at the B.M.A. Annual Meeting there in 1920. For some years he lectured on immunity to the D.P.H. classes. Nothing would ever persuade Harvey to consider leaving his beloved Cambridge, but family needs made him give up pure research, and take up clinical pathology, which he practised for the rest of his active life, being bacteriologist to the borough and county of Cambridge; but he remained a research man at heart. He had an original, unworldly mind, and like a true pioneer he always questioned the axioms.

Dr. STUART ERNEST GORDON, who died on Nov. 18, was born in Dublin on Oct. 17, 1889, son of the late Alexander Gordon, L.R.C.P. He was educated at St. Andrews and Wesley Colleges, Dublin, and studied medicine at the School of the Royal Colleges of Physicians and Surgeons. After qualifying in 1915 he held resident posts at the Newcastle Sanatorium, Co. Wicklow, and at the Norwich City Asylum, Norfolk. He was in general practice for a time and then took up tuberculosis work at the Middleton-in-Wharfedale Sanatorium, Ilkley, and at the Ashover Sanatorium near Chesterfield.

Dr. C. Thackray Parsons writes: The first reaction of many of HARRY ROBERTS's intimate friends to the broadcast announcement of his death must have been the same as mine—"It is impossible." We knew how precarious his hold on life was, but it seemed as if his personality, will, and mental activity were keeping death at bay and might continue to do so. His was a full life, full of many activities and many achievements. He had a passionate love for freedom and for humanity. A lifelong Socialist, he dreamed of a Commonwealth organized to produce at the least possible cost in distasteful work and leaving each member free to live his own life in his leisure. He was friends with all men, but he sought most those who were unusual and unconventional, if they were free from pretence. He assumed a veil of cynical humour which failed to hide the warmth of his feeling for all who were wounded in the struggle of life, and for what he held to be righteous and true. His energy was inexhaustible. What he did in the East End of London, in Petersfield, and in Hawkey brought him hosts of friends and of workers who looked to him for guidance. He has left a memory that will endure. An original thinker, his mind stored with the best in literature, he was able to clothe his thoughts in words of beauty and force both in his writings and in his talk. He loved to gather friends around him, to interchange thoughts and discuss problems. With his clear and logical mind he was quick to seize upon a fallacy in an argument and to expose it mercilessly and wittily without leaving any aftertaste of bitterness. His life was an inspiration, and when so many charmed memories remain there is no death.

The following appreciation of Dr. WILLIAM HENRY PEACOCK comes from Prof. R. M. Gordon: The loss sustained by the Colonial Medical Service through the death of Dr. Peacock has already been recorded in the *Journal*. The announcement of his death will have been read with sorrow by all who have interested themselves in furthering medical projects in West Africa. It was characteristic of the man that his help and kindness extended far beyond his official duties, and reached out to all who, like himself, were interested in alleviating suffering. It was in this way that each newcomer to the Sir A. L. Jones Research Laboratory (of the Liverpool School of Tropical Medicine) in Freetown came to know and trust Peacock, and to appreciate his sound common sense, his very considerable medical knowledge, his gift of foreseeing and eliminating obstacles both official and unofficial, and above all his loyalty and devotion not only to the Service in which he worked but to the profession which he so finely represented.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Sir Edward Mellanby, K.C.B., M.D., F.R.S., Secretary of the Medical Research Council, has been elected into an Honorary Fellowship of Emmanuel College.

At a Congregation held on Nov. 16 the following medical degrees were conferred:

M.B., B.Chir.—N. H. Harwood-Yarred and W. A. A. Hodges (by proxy). H. G. Mather (in person).

UNIVERSITY OF LEEDS

At a meeting of the Council, held on Nov. 27, the Pro-Chancellor drew attention to the recent losses by death of two emeritus professors—J. Shaw Bolton and T. Wardrop Griffith—and referred to the valuable services which they had given to the University as professors for twenty-two and thirty-eight years respectively.

Dr. R. N. Tattersall was appointed full-time lecturer in medicine, and Dr. D. Taverner tutor in medicine.

UNIVERSITY OF MANCHESTER

The Council has appointed Alexander Michael Boyd, F.R.C.S., a full-time Professor of Surgery and Director of the Department of Surgery, from Dec. 25.

UNIVERSITY OF EDINBURGH

Prof. R. J. Kellar, F.R.C.S.Ed., F.R.C.O.G., who has succeeded Prof. R. W. Johnstone in the University Chair of Midwifery and Diseases of Women, gave his inaugural lecture on Nov. 14 in the Pollock Memorial Hall, with the Principal, Sir John Fraser, in the chair. Discussing the modern trend of maternity hospitals Prof. Kellar expressed the view that some 75% of all women in urban areas would be delivered in institutions, and any calculation of future needs in maternity accommodation must use this as a minimum figure. It might be taken as an axiom that a maternity hospital was out of date in many of its features within a decade of its construction, and he recalled that Sir J. Y. Simpson had seriously proposed burning a maternity hospital every few years to rid it of puerperal infection. Prof. Kellar said that Edinburgh might be regarded as the birthplace of antenatal care. But notwithstanding the saving of lives each year most of them were extremely dissatisfied with certain aspects of the antenatal clinic. This must become in future more of a social centre, where the patient could receive not merely a brief intensive abdominal examination, but also instruction in elementary hygiene, in preparation for delivery, and in infant management. More antenatal beds were needed. Again, the time might be ripe for setting up some central organization to deal with all the problems of abortion, stillbirth, infertility, and population trends. Child guidance and marriage guidance clinics would have much to gain in association with such a group, which might well be a subdivision of the Department of Social Medicine. The managers of the Edinburgh Royal Infirmary had allotted accommodation for a clinical research laboratory within the precincts of the Maternity Hospital, and this might well work in conjunction with the new extended University Department.

UNIVERSITY OF GLASGOW

Sir John Boyd Orr, M.D., F.R.S., has been elected Chancellor of the University of Glasgow. The election was conducted by postal ballot and resulted in 6,113 votes for Sir John Boyd Orr and 5,420 for Sir Iain Colquhoun.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Primary F.R.C.S. Examination Overseas

The Council of the Royal College of Surgeons of England, having acceded to requests from the Royal Australasian College of Surgeons, from the medical faculty of the Egyptian University, Cairo, and from the Director-General of Medical Services in India, to conduct the Primary F.R.C.S. examination overseas, has appointed the following examiners for this purpose: Sir Heneage Ogilvie, Prof. B. A. McSwiney, F.R.S., and Prof. G. Hadfield. They will conduct the examination in Cairo, Madras, Melbourne, Sydney, and Dunedin, beginning in Cairo on Dec. 12, in Madras on Dec. 23, and in Australasia on Jan. 6. The examiners should arrive back in this country about the end of January.

The extent to which the facilities thus offered to those medical graduates of recognized universities and colleges overseas are appreciated may be indicated by the numbers who have entered for the examination at the several centres: Cairo, 32; Madras, 65; Melbourne, 63; Sydney, 29; and Dunedin 35, a total of 224 candidates. In due course those candidates who satisfy the examiners will

be eligible to appear for the final F.R.C.S. examination in this country, and will have the opportunity of studying surgical practice in England.

The following associate examiners have been appointed to assist the examiners: In Cairo, Prof. D. E. Derry and Prof. G. V. Anrep, F.R.S. In India, Prof. A. Ananthanarayana Iyer. In Melbourne, Prof. S. Sunderland. In Sydney, Mr. Douglas Miller. In Dunedin, Mr. John Cairney.

A course of 72 lectures in anatomy, applied physiology, and pathology will begin at the College on Feb. 3, 1947, and will continue until March 28. There will be two lectures daily (Monday, Tuesday, Wednesday, Thursday, and Friday) at 3.45 p.m. and 5 p.m. The fee for the whole course is £15 15s. Fellows and Members of the College and licentiates in dental surgery will be admitted on payment of a fee of £10 10s. It will not be permissible to take one or two subjects only. Applications, accompanied by a cheque for £15 15s. or £10 10s., should be sent to the assistant secretary, Royal College of Surgeons of England, Lincoln's Inn Fields, W.C.2.

Practical demonstrations in anatomy, applied physiology, and pathology have been arranged by Profs. F. Wood Jones, John Beattie, and R. A. Willis, and will be given from Monday, Jan. 6, to Friday, March 28, 1947, from 10 a.m. to 1 p.m., and from 2 to 3.30 p.m. daily. The fee is £21, and the closing date for applications is Dec. 16. The demonstrations will be open to those attending the main course of lectures to be held in Feb. and March and will be limited to 40 students, preference being given to those unable to obtain practical instruction elsewhere and to ex-Service men. Applications, accompanied by a cheque for £21, should be sent to the assistant secretary, Royal College of Surgeons of England, Lincoln's Inn Fields, W.C.2.

The Services

Surg. Rear-Admiral J. A. Maxwell, C.B.E., C.V.O., R.N., has been appointed an Honorary Surgeon to the King in succession to Surg. Rear-Admiral H. R. B. Hull, R.N., who has been placed on the retired list.

Surg. Capt. Lambert C. Rogers, and Surg. Lieut.-Cmdrs. C. M. Lamont and A. B. Bateman, R.N.V.R., have been awarded the R.N.V.R. Officers' Decoration.

Surg. Capt. D. A. Pritchard and L. Lockwood, M.V.O., D.S.C., R.A.N., have been appointed Honorary Physician and Honorary Surgeon to the King, respectively.

Lieut.-Col. J. Morrison, O.B.E., M.C., and Major H. Mannington, R.A.M.C., have been awarded the Efficiency Medal (Territorial).

Cpts. J. H. Annan and G. McL. Gorrie, R.A.M.C., have been mentioned in dispatches in recognition of gallant and distinguished services in the field.

Col. J. F. O'Grady, T.D., R.A.M.C., T.A., to be Honorary Colonel, 42nd (East Lancashire) Division, R.A.M.C., in succession to Col. A. M. Johnson, C.B.E., M.C., T.D., R.A.M.C., T.A., deceased.

Capt. T. R. Subramaniam, I.A.M.C., has been appointed M.B.E. (Military Division) in recognition of gallant and distinguished services in S.E. Asia.

CASUALTIES IN THE MEDICAL SERVICES

On or after Oct. 18, 1942, while a prisoner of war in Japanese hands.—Capt. James Walsb Lillico, I.M.S.

Flying Officer CHARLES KING ALLAN, R.A.F.V.R., who was killed in a flying accident on Nov. 7, was born in December, 1922, studied medicine at Glasgow University, and qualified M.B., Ch.B., in 1945.

AIRBORNE MEDICAL SOCIETY

It has been decided to enlarge the membership of the Airborne Medical Society, the formation of which was announced in the *Journal* of Aug. 24 (p. 282), to include all medical and dental officers who are eligible for membership of the Airborne Forces Club. That, in fact, includes all medical and dental practitioners whose business it was or is to go to war by parachute or glider. Quartermasters and transport officers of airborne field ambulances are also eligible. Application forms may be obtained from the honorary secretary, Airborne Medical Society, 63a, Belsize Park Gardens, London, N.W.3.

The Ministry of Health announces in Circular 193/46 the removal of restriction on the engagement of chiropodists, physiotherapists, radiographers, hospital almoners, pharmacists, dispensers, and psychiatric social workers; and the procedure for securing staff in these categories.

Medical Notes in Parliament

The National Health Service (Scotland) Bill was presented by Mr. Westwood on Nov. 26 and was read a first time. The Bill had already been formally introduced and printed late last session.

Medical Unemployment

Answering Mr. SOMERVILLE HASTINGS on Nov. 28, Mr. BEVAN regretted that he did not know how many ex-Service doctors were unable to obtain employment in general practice. Ex-Service general practitioners could take hospital posts and refresher courses available under the Government's post-graduate scheme. It was then open to them to buy or open a practice or to seek assistantships or other appropriate employment in the usual way until the National Health Service Act came into operation. He was aware that there was at present a difficulty in doctors obtaining assistantships. It was a difficulty which always arose immediately before great changes. The Ministry of Health was doing its best to mitigate the hardships where it could.

Temporary Registration

Mr. BEVAN, on Nov. 28, told Sir HENRY MORRIS-JONES that he and Mr. Ede were consulting about temporarily registered alien doctors. He was not yet in a position to make a statement. There was no provision for temporary registration of alien dentists apart from a few practising solely by virtue of temporary medical registration. Those admitted to the dentists' Register had secured admission in the ordinary way. He imagined that under the new National Health Service Act all persons who were competent to practise would be competent to enter.

Penal Reform

Replying on Nov. 27 to a debate in the House of Lords on penal reform, the LORD CHANCELLOR, Lord Jowitt, said the comprehensive Bill of 1938 would need to be reconsidered by the present Government. It was impossible to introduce this Bill this session, but he thought it was almost certain to be one of the major Bills introduced next session. The Government would use the interval in pressing ahead with probation and Borstal treatment.

LORD TEMPLEWOOD, in his introductory speech, said that during the war years young offenders under 17 had increased by 55%. In offenders between 17 and 21 the increase had been 52%, and in offenders over 21 it had been 2%. Comparing 1938 with 1945, crimes against the person had increased from 1,583 to 2,459, and sexual offences from 2,321 to 3,228. Offences committed by women had more than doubled during the war. Women's convictions for cruelty to children had increased from 345 to 1,170. Among young delinquents offences of every category by girls had gone up fourfold.

Prescriptions for Dangerous Drugs.—On Nov. 21 Dr. CLITHEROW asked whether Mr. Bevan knew that prescriptions for dangerous drugs and scheduled drugs were being issued to national health insurance patients in quantities sufficient, in many cases, to ensure a constant supply for many weeks—for example, 200 barbitone tablets in one case. He asked Mr. Bevan to take steps to prevent the issue of N.H.I. prescriptions containing dangerous drugs and scheduled drugs for more than one week's supply at any one time. Mr. BEVAN said that he did not think it would be proper to interfere with a doctor's discretion by any such general prohibition.

Medical Students Not Admitted.—Statistics given by Mr. GLENVIL HALL on Nov. 26 show that of students possessing the certificate of fitness for entrance to a Scottish University 238 made application for admission for the Session 1946-7 to the faculty of medicine, including dentistry, in Aberdeen. Of these 119, or 50%, were refused admission. Comparable figures for the same faculty were: Edinburgh 827-637, or 77%; Glasgow 760-334, or 43.9%; St. Andrews 501-398, or 78%.

Social Surveys.—Mr. GLENVIL HALL announced on Nov. 25 that the Social Survey of the Central Office of Information was engaged on an illness survey for the Ministry of Health, and was preparing for the Medical Research Council a report on the incidence of deafness in this country. A report was now being written for the Medical Research Council and the Ministry of Fuel and Power on the employment of miners certified as suffering from pneumoconiosis.

Ice-cream.—Mr. STRACHEY would like to fix a minimum standard for ice-cream but thinks this must wait until the supply of the necessary ingredients has improved.

Medical News

Abstracts of World Medicine and Abstracts of World Surgery, Obstetrics and Gynaecology will make their first appearance in January, 1947. These two new journals are being published monthly by the British Medical Association, the first at an annual subscription of 3 guineas and the second at 2 guineas. Applications for subscription should be sent to: The Publishing Manager, *British Medical Journal*, B.M.A. House, Tavistock Square, London, W.C.1.

A joint meeting of the Food Group and the Manchester Section of the Society of Chemical Industry will be held at the Engineers' Club, Albert Square, Manchester, on Friday, Dec. 6, at 6.30 p.m., when papers will be read by Dr. N. J. Berridge on "Rennin," by Mr. H. F. Frost on "Enzymes in the Food Industry," and by Mr. S. Hilton on "Soft Curd Milk." Time will be allowed for discussion.

The fourth quarterly meeting of the Franco-Anglo-American Medical Society will be held at 11, Chandos Street, Cavendish Square, W., on Tuesday, Dec. 10, at 2.30 p.m., with Lord Horder, president of the British Section, in the chair.

A meeting of the Nutrition Panel of the Society of Chemical Industry will be held at the Chemical Society's rooms (Burlington House, Piccadilly, W.) on Wednesday, Dec. 11, at 6.30 p.m., when Mr. D. P. Hopkins will read a paper on "Fertilizers, Manures, and Nutrition." A discussion will follow. Members of the Agriculture and Food Groups are invited to attend.

A meeting of the Middlesex County Medical Society will be held at Redhill County Hospital, Edgware, on Thursday, Dec. 12, at 4 p.m., when there will be clinical demonstrations.

Sir Arthur MacNalty will deliver the FitzPatrick Lectures at the Royal College of Physicians of London, Pall Mall East, S.W., on Tuesday, Dec. 10, and Thursday, Dec. 12, at 5 p.m. The subject will be the History of State Medicine in England: (1) From the Accession of Queen Victoria to the General Board of Health, (2) The Medical Department of the Privy Council.

Mr. W. Rowley Bristow will deliver the Robert Jones Memorial Lecture on "Injuries of Peripheral Nerves in Two World Wars" before the Royal College of Surgeons of England (Lincoln's Inn Fields, W.C.) on Thursday, Dec. 12, at 5 p.m.

A sessional meeting of the Royal Sanitary Institute will be held at the Baths Hall, Leigh Street, Warrington, on Friday, Dec. 13, at 10.30 a.m., when papers will be read by Dr. S. F. Allison on "The Welfare of Old People" and by Dr. J. E. Nicole on "The Mental Health of the Elderly."

The Medical Society of London announces that Sir James Chadwick will deliver the Lloyd Roberts Lecture at 11, Chandos Street, W., on Monday, Dec. 16, at 8.30 p.m. Subject: "Atomic Energy."

A meeting of the Eugenics Society will be held at the Royal Society's rooms (Burlington House, Piccadilly, W.) on Tuesday, Dec. 17, at 5.30 p.m., when Dr. J. W. B. Douglas will speak on "Social and Economic Problems of Child-bearing in Britain: Report of a Questionary Inquiry." All interested in the subject are invited to attend the meeting.

Sir Alexander Fleming, F.R.S., will give a talk on "Penicillin in General Practice" before the Paddington Division of the B.M.A. in the Inoculation Department of St. Mary's Hospital, W., on Thursday, Dec. 19, at 8.30 p.m. Members of other Divisions are invited to attend the meeting.

On Nov. 7 Mr. de Vajera introduced in the Dail a Bill to establish two new Ministries for Eire—a Ministry of Public Health and a Ministry of Social Welfare.

In future, hospitals and members of the medical profession should address all inquiries concerning laboratory chemicals to the British Drug Houses Ltd., B.D.H. Laboratory Chemicals Group, Poole, Dorset (Tel.: Poole 962; telegrams: Tetradome Poole), and not to the British Drug Houses Ltd., Graham Street, London, N.1.

Dr. V. Puddu, Director of a Rome clinic for rheumatic and heart diseases, is visiting this country on behalf of the Italian Ministry of Health to study British arrangements for treating rheumatism and heart diseases, particularly in children's hospitals.

Dr. Joaquim Paiva Chaves, a Lisbon surgeon, is visiting Britain to study problems of traumatic surgery under Sir Reginald Watson-Jones at the London Hospital, and to visit other hospitals to see general traumatic and repair surgery. The British Council has assisted in arranging his programme.

Fifty doctors from London and Southern England were recently entertained by the Southern Railway at a luncheon in London in recognition of their help in instructing railway ambulance workers.

IT'S AN ABBOTT RESEARCH PRODUCT

Pre-eminence by merit . . .

During the past difficult years PENTOTHAL was being continuously produced in ENGLAND to meet every need and in an ever-widening sphere of applicability has conclusively PROVED its pre-eminence in the field of intravenous anaesthesia. Year by year, reports prepared with exhaustive thoroughness and exclusively devoted to the application of PENTOTHAL have been published by eminent surgeons and anaesthetists detailing indications and contraindications, advantages and disadvantages, techniques of administration and precautions.

WE STOOD ALONE!

Descriptive literature will be sent on request.

Vitamins in Obstetrics

For more than 18 years Vitamins Ltd., have been working on nutritional subjects. During that time, dramatic advances have been made in the recognition of deficiency conditions and diseases, and in the appropriate uses of vitamin therapy.

In pregnancy, when dietary requirements are raised, it is important to take prophylactic measures against the development of latent deficiencies.

Condition	Indications	Therapeutic Agents
STERILITY Sub-sterility Habitual or threatened miscarriage	These conditions when not traceable to structural or endocrine abnormalities may be associated with a deficiency of vitamin E.	FERTILOL (Wheat germ oil stabilised and standardised) 1 to 3, 3 mg. caps. daily. BEMAX contains vitamin E (8 mg. per oz.) and other factors which may be important.
PREGNANCY TOXAEMIAS	May arise when the extra demands of pregnancy are not met in the diet.	PREGNAVITE TABLETS . A comprehensive dietary supplement designed to meet the pregnancy requirements of the important vitamins and minerals.
HYPEREMESIS GRAVIDARUM	May be one sign of the above.	VITAMIN B₆ (Pyridoxin), Vitamins Ltd., 10 to 20 mg. thrice daily. VITAMIN B₁ (Aneurin hydrochloride), Vitamins Ltd., 10 mg. or more daily.
OEDEMA	As in beri-beri and congestive failure may in some cases be associated with vitamin B ₁ deficiency.	VITAMIN B₁ (Aneurin hydrochloride), Vitamins Ltd., 3 to 10 mg. daily.
HAEMORRHAGE in the new-born	To raise prothrombin levels in the first days of the infant's life.	VITAMIN K , Vitamins Ltd., 10 mg. tablets, one daily to the mother or the contents of 1 Ampoule to the infant.

Further particulars of the various products are obtainable on request from

Vitamins Limited

(Dept. B. X. F.2), Upper Mall, London, W.6.

SIMULTANEOUS

IMMUNISATION now possible against DIPHTHERIA and PERTUSSIS

Most parents responding to the campaign in favour of diphtheria immunisation readily agree to the inoculation of their children against whooping cough at the same time. Simultaneous prophylaxis against both infections can now be achieved with Diphtheria Prophylactic A.P.T. plus Pertussis Vaccine (alum-precipitated), introduced by Glaxo.

This preparation contains in each 1 cc. at least Lf 25 diphtheria prophylactic and 20,000 million H. pertussis. Administered together, each antigen enhances the effect of the other. One course of three injections (0.5 cc., 0.5 cc., and 1 cc. at intervals of four weeks) condenses the immunisation procedure into a conveniently manageable span. Immunisation at 4 to 6 months of age with this new injection of 'combined antigens' gives subsequent protection over a period of child life in which diphtheria and whooping cough can be most deadly.

**DIPHTHERIA PROPHYLACTIC A.P.T. PLUS
PERTUSSIS VACCINE (ALUM-PRECIPIATED) Glaxo**

PHENOXYETOL

P.E.E.G.

THE ANTI-PSYOCYANEA COMPOUND

HERE is an important new bactericide and antiseptic. Phenoxyetol (Nipa) is B-phenoxethyl-alcohol, specially purified and standardised, for use in medical treatment and for pharmaceutical preparations.

Phenoxyetol is effective against certain gram-negative organisms, including *Ps. pyocyanea*. It is used by local application in the treatment of infected wounds . . . abscesses . . . indolent ulcers . . . associated with *Ps. pyocyanea*. It should not be used for parenteral injections.

Phenoxyetol is very effective in pyocyanea infections of burns or superficial wounds. It is especially useful in the preparations of surfaces for skin grafting associated with *Ps. pyocyanea*, and may also be used together with Penicillin in solutions and creams.

At a meeting of the executive committee of the Anglo-Soviet Medical Council on Nov. 13 the hon. secretary, Dr. D. E. Bunbury, reported on the present position. Throughout the year copies of British medical journals have been sent regularly to the Soviet Union by the Council. The British Council also sent 50 copies of each issue of the *British Medical Bulletin*, and a member of its staff is resident in Moscow. Soviet journals for the A.S.M.C. have been arriving irregularly throughout the year. These have been housed in the Royal Society of Medicine and have been presented to the Society's library when the Council has finished with them. Journals have been made available to the editors of the British medical abstract journals. The World Medical Association, which was formed during the year on the initiative of the British Medical Association, should be able to take over the broadest aspects of the Council's work in relation to the Soviet Union, as with other countries. The Society for Cultural Relations with the U.S.S.R. is willing to deal with specific inquiries concerning Soviet medicine, and might form a medical section with functions similar to its existing scientific and other sections. After consideration of all aspects of the present position, the executive committee decided to make recommendations to the Council for adoption at the fifth annual general meeting, to be held on Dec. 9, at 5 p.m., at 1, Impole Street.

The first meeting of the Pharmaceutical Liaison Committee, set up in July, 1946, to improve contact between the Ministries of Health and of Supply and the pharmaceutical profession, was attended by representatives appointed permanently from the Pharmaceutical Society, the British Pharmacopoeia Commission, the National Pharmaceutical Union, the Wholesale Drug Trade Association, and the Pharmaceutical Export Group on the one hand, and of the Ministry of Health, the Department of Health for Scotland, the Ministry of Supply, Ministry of Food, the War Office, the Admiralty, and the Air Ministry on the other.

The result of the Scottish Universities by-election was announced on Nov. 29. The Right Hon. Walter Elliot (Conservative) was returned to Parliament with a poll of 22,152 votes.

Dr. William Russell Cooper, of Clifton, Bristol, left £16,317 to the University of Bristol, upon trust, the annual income to be paid to the medical student considered to be the most proficient at anaesthetics. After other bequests to medical friends and £300 to the Cancer Hospital, London, he had left the residue of his property to Bristol General Hospital, but by codicil dated Oct. 17, 1945, he altered this, saying, "the Government being about to take over the management of the said hospital should be responsible for its upkeep."

EPIDEMIOLOGICAL NOTES

Discussion of Table

In England and Wales infectious diseases increased in prevalence. Rises were recorded in the incidence of measles 395, whooping-cough 106, acute pneumonia 24, and diphtheria 16; the only falls were in the notifications of scarlet fever 30 and cerebrospinal fever 16.

The largest increases in the returns for measles were Durham 18, Lancashire 86, Yorkshire West Riding 56, Middlesex 43, Devonshire 42, and Dorsetshire 40. The largest fluctuations in the local incidence of whooping-cough were increases in Yorkshire West Riding 34, Lancashire 29, and London 25. The chief changes in the notifications of diphtheria were a rise in Lincolnshire 10 and a fall in Lancashire 14. Cases of paratyphoid fever were notified in Yorkshire West Riding, Sheffield C.B. 14, and in Glamorganshire 6. London, with an increase from 13 to 23, provided the only appreciable change in the incidence of dysentery; 14 of the cases were notified in Islington.

In Scotland increases were recorded in the notifications of whooping-cough 48, measles 32, acute primary pneumonia 32, and diphtheria 9. Decreases were reported for scarlet fever 46 and dysentery 26. The rise in the number of cases of diphtheria was due to an increase from 68 to 80 in the Western Area.

In Eire there were 18 fewer cases of diarrhoea and enteritis and 39 more cases of whooping-cough. The two large centres of infection for whooping-cough were Co. Laoighis, Mountmellick R.D. 40 and Dublin C.B. 21.

In Northern Ireland increases occurred in the notifications of measles 20 and diphtheria 7 and a decrease was reported for whooping-cough 11.

Week Ending November 23

The notifications of infectious diseases during the week in England and Wales included: scarlet fever 1,402, whooping-cough 1,773, diphtheria 319, measles 5,428, acute pneumonia 708, cerebrospinal fever 43, dysentery 69, acute poliomyelitis 16, paratyphoid 20, typhoid 3.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Nov. 16.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1946					1945 (Corresponding Week)

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

It is still not possible to publish the returns of births and deaths for Eire for the weeks ended Oct. 26, Nov. 2, 9, and 16.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Attilology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate, Westcent, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra, Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Ehrlich's Reaction in Infective Hepatitis

Q.—I should be grateful for advice on the technique and interpretation of Ehrlich's dimethylaminobenzaldehyde reaction as applied to the early diagnosis of infective hepatitis.

A.—The technique recommended for this test is that of Watson, Schwartz, Sborov, and Bertie (*Amer. J. Clin. Path.*, 1944, 14, 605), in which the amount of urobilinogen is estimated in a two-hour afternoon specimen of urine, the result being expressed in units which are approximately mg. per 2 hours. Alternatively the test may be used qualitatively by adding one volume of Ehrlich's reagent (0.7 g. *p*-dimethylaminobenzaldehyde, 150 ml. concentrated hydrochloric acid, 100 ml. water) to one volume of urine, followed, immediately after shaking, by three volumes of saturated sodium acetate. A definite red colour indicates excessive amounts of urobilinogen. It is important to test only fresh specimens.

In interpreting the result it must be remembered that many febrile patients may show evidence of transient liver dysfunction with positive urobilinogen tests, and that a positive result is not therefore pathognomonic of infective hepatitis; moreover, negative tests are occasionally seen in this condition. However, urobilinuria is certainly to be expected in most cases and often occurs well before the appearance of clinical jaundice.

T.A.B. for Children

Q.—At what age should children travelling to the Far East be given prophylactic injections of T.A.B. and anti-cholera vaccine?

A.—Recorded examples of typhoid fever in infants are rare, and consequently it is suggested that infants and young children possess a relative immunity to the disease and that protective inoculation is therefore unnecessary. This is probably true, but it must be remembered that special care is usually taken in preparing the food of infants who are in circumstances favourable to medical observation, and that as regards other children less favourably placed the paucity of precise observations may account for the apparently low incidence of the disease. A further argument adduced against the inoculation of infants is that there is some experimental evidence that antibody formation following inoculation in the early months of life is relatively poor. Nevertheless, since the immediate local and general reactions to inoculation usually are not abnormally severe in infants or small children, there seems little reason for not giving them such protection as may result from, inoculation; consequently it is suggested that children of any age should be given prophylactic T.A.B. and cholera vaccine in appropriate doses when travelling to the Far East.

Mepacrine Dosage for Children

Q.—At what age and in what dosage should mepacrine be given (a) prophylactically, (b) therapeutically?

A.—Unless a child can be protected against the bites of infected mosquitoes it would seem wise to give it a suppressive antimalarial drug, and mepacrine may be used until one of the more efficient drugs, such as paludrine, becomes generally avail-

able. The relative dose of a drug depends more upon the metabolic rate of the individual than upon age, and consequently children tend to tolerate larger doses than would be suggested by age alone.

The ratio of dosage between child and adult is not two-thirds the ratio of the child's weight to that of the adult, but is the ratio raised to the two-thirds power, and this relation may be used for calculating the appropriate suppressive or therapeutic dose of mepacrine for a child of any age.

$$\frac{\text{Dose child}}{\text{Dose adult}} = \frac{\text{Metabolic rate child}}{\text{Metabolic rate adult}} = \frac{\text{Surface child}}{\text{Surface adult}} = \frac{(\text{Weight child})^{2/3}}{(\text{Weight adult})^{2/3}} = \left(\frac{W_c}{W_a}\right)^{2/3}$$

Approximations worked out on the above formula, assuming a normal adult of 168 lb. (12 st. or 76 kg.), are as follows

For child of weight	10 lb. (4.5 kg.)	give	1/8 of adult dose
"	20 " (9 kg.)	"	1/4 " "
"	30 " (13.5 kg.)	"	1/3 " "
"	60 " (27 kg.)	"	1/2 " "
"	90 " (40.5 kg.)	"	2/3 " "
"	110 " (49.5 kg.)	"	3/4 " "
"	120 " (54 kg.)	"	4/5 " "

Dicoumarol for Coronary Thrombosis

Q.—Has any work been done in this country on dicoumarol which is being used in America in the treatment of coronary thrombosis?

A.—There was a paper by Davis and Porter in this *Journal* (1944, 1, 718) on the use of dicoumarol in puerperal thrombosis. It has also been used for post-operative thrombosis by Prof. Learmonth in Edinburgh. A paper by Barker, Cromer, Hurst, and Waugh (*Surgery*, 1945, 17, 207) gives useful information about the contraindications. Several other publications on the use of this anticoagulant in coronary thrombosis have appeared during this year in American publications. I am not aware of any papers on this subject in English journals.

Dicoumarol is being used in coronary disease with the aim of preventing retrograde extension of a thrombus and consequent aggravation of the cardiac lesion, and also with the object of lessening the likelihood of multiple thrombi and other complications. A trial of dicoumarol therapy is therefore indicated when a patient is not making a quick and progressive recovery after coronary thrombosis; when there is evidence of multiple thrombosis, mural thrombus, or pulmonary embolism; and when a patient is threatened with multiple successive attacks. Before treatment is begun the prothrombin time is determined. If this is 17 seconds or less 300 mg. of dicoumarol are administered orally in one dose. This dose is repeated daily until the prothrombin time is 30 seconds. Doses of 100 or 200 mg. are given daily when the prothrombin time is between 30 and 35 seconds; above this level the dosage should be discontinued owing to the risk of haemorrhage. An attempt is usually made to pursue this treatment for about a month after the last evidence of thrombosis or embolism. No series of cases sufficiently large or controlled to judge finally the efficacy of this treatment has yet been published, but the consensus seems at this stage to be favourable.

Deodorants

Q.—What are the constituents of the usual deodorants? Are such preparations harmful if used repeatedly? Would there be any advantage in using them for pre-operative skin preparation, and, post-operatively, to prevent perspiration?

A.—The majority of liquid deodorants contain one or other, or a combination, of the numerous mild astringents, such as dilute alcohol, alum, zinc sulphate, formaldehyde, dilute acetic acid, and so on, sometimes coloured and perfumed. As they are not curative but merely a symptomatic treatment for excessive perspiration they have to be used repeatedly. Except in the case of persons who are hypersensitive their repeated use does not appear to be detrimental. Most of them are only very mildly, if at all, antiseptic, and it is unlikely that there would be any advantage in using them for pre-operative skin preparation, or post-operatively. They are usually applied by means of cotton-wool or gauze dabbed or rubbed lightly over the surface. The nature of the deodorant being used would of course determine its compatibility with the usual antiseptics, but it is probable that incompatibility would be experienced with most of them.

Inheritance of Little's Disease

Q.—*A patient has one child suffering from Little's disease. There was no birth injury, and the labour was normal. What are the chances of any future children being similarly affected?*

A.—Little's disease or congenital spastic diplegia is probably not a single clinical entity. Some cases may be due to birth injury, others to foetal malnutrition, prenatal infection, or to unknown environmental causes. A fairly large proportion of the cases are due to recessive genes. In complete ignorance of the cause, as in this particular case, the chances of recurrence of the abnormality in a subsequent pregnancy can be only roughly estimated at one in twenty. However, no accurate assessment can be given until careful inquiry has been made into the possible incidence of similar conditions in near relatives. Even if such inquiry leads to negative results but the parents are found to be cousins, the case is probably of recessive genetic origin, and the chance of recurrence is one in four. A search for incompatibility of Rh or of ABO antigens in mother and child might also yield some relevant information.

Penicillin for Osteomyelitis

Q.—*A man of 27 had osteomyelitis of the left leg following an air-raid injury in 1943; this cleared up after nearly eight months in hospital. Since then he has had twenty-four axillary abscesses. Would penicillin injections be of any value in such a case?*

A.—If these abscesses are metastatic, a focus of osteomyelitis still existing in the left leg or elsewhere, penicillin treatment alone would be useless. It usually fails in any chronic infection depending on the continued existence of an old-standing focus, particularly if this is located in bone. Organisms situated in a chronic abscess cavity or in an area of necrosed bone cannot be eradicated completely by penicillin, if only because such an area is not adequately permeated by the drug.

Uterine Haemorrhage after Synthetic Oestrogens

Q.—*A woman of 51 has an erythematous condition of her face. A specialist prescribed 1 mg. stilboestrol daily for two months, then one month's rest. She now has uterine bleeding, though her menopause was three years ago, and is worried about the possibility of pregnancy. Can I reassure her that stilboestrol does not cause ovulation after the menopause and that pregnancy cannot supervene?*

A.—The uterine haemorrhage which may follow oestrogen therapy is anovular in type and is not true menstruation. Stilboestrol, at any rate when continuously applied, does not cause ovulation; indeed it depresses ovarian activity. The chances of pregnancy are therefore extremely remote and certainly no greater than if the stilboestrol had not been given.

The reawakening of endometrial activity is, however, a disadvantage in itself. If the treatment is continued endometrial hyperplasia and profuse bleeding may result. Already the case is one of "post-menopausal bleeding," and though the cause is probably the stilboestrol there remains the possibility that the patient may have a growth in the uterus. If it has not already been done a pelvic examination should be made to exclude any obvious lesion in the vagina and cervix. The dose of stilboestrol should be reduced or, unless the skin condition is clearly benefiting from it, the treatment discontinued. If in spite of this the bleeding continues or recurs then the only safe line of action is to carry out diagnostic curettage.

Blood Thiocyanate Estimations

Q.—*Please describe the biochemical technique for the estimation of blood thiocyanate levels in cases of hypertension under treatment with potassium thiocyanate.*

A.—Three solutions are needed for the estimation of thiocyanate in serum and plasma: (a) 10% trichloroacetic acid. (b) Ferric nitrate reagent—dissolve 20 g. crystalline ferric nitrate in 500 ml. distilled water; add 25 ml. concentrated nitric acid. (c) Thiocyanate standard (stock solution)—dissolve about 1 g. potassium thiocyanate in 500 ml. distilled water; titrate 20 ml. of a standard silver nitrate solution (made by dissolving 2.9195 g. silver nitrate in 1,000 ml. water) acidified with 5 ml.

concentrated nitric acid against the thiocyanate solution, using ferric ammonium sulphate as an indicator; add the water necessary to make 20 ml. thiocyanate equivalent to exactly 20 ml. silver nitrate solution; check.

To 5 ml. of solution (a) add 5 ml. plasma or serum, shake well and stand for fifteen minutes; filter—the filtrate must be perfectly clear; measure 5 ml. filtrate and to it add 1 ml. of ferric nitrate reagent (b). Make three dilutions of stock thiocyanate solution: 100 ml. in a litre of water; 70 ml. in a litre of water; and 40 ml. in a litre of water (equivalent to 1.0 mg., 0.70 mg., and 0.40 mg. in 5 ml.). To 2.5 ml. of these three standards in three test-tubes add 2.5 ml. of solution (a) and 1 ml. of solution (b). Read the unknown against the standard in a colorimeter, using the standard which it most nearly matches.

It should perhaps be pointed out that since the appearance of Barker's work (*J. Amer. Med. Ass.*, 1936, 106, 762 and 1941, 117, 1591) the original theory that thiocyanate is deficient in hypertensive blood has been disputed. Later determinations have shown a normal content, and clinical experience of the thiocyanate treatment in this country has not fulfilled the hopes held out for it originally by American workers.

INCOME TAX

Car Transactions

R. M. bought an "M" car in 1940 for £180; he sold it in March, 1946, buying an "R" car for £710. No depreciation allowance has been claimed.

* We suggest that he claims depreciation on the "M" car for the six years 1941-2 to 1946-7 inclusive; the claim should be made under Section 45 of the Finance Act, 1927, on the ground that overcharges have resulted from "errors or omissions in the returns." The amounts of depreciation apparently claimable are: 1941-2, £43; 1942-3, £35; 1943-4, £28; 1944-5, £21; 1945-6, £18, and 1946-7, £14. No depreciation in respect of the "R" car is due for 1946-7, but, assuming that the accounts of the practice are made up to Dec. 31 each year, allowance will be due for 1947-8 as follows:

Initial Allowance	20% of £710=£142
Depreciation Allowance	25% of £710=£178
Total	£320

Post-demobilization Appointment

"Resident" holds a Class 3 post-demobilization appointment. His salary is £550, which is paid by the hospital but made good by the Exchequer. Is the salary liable to income tax? If so, can the cost of journals and textbooks be claimed as a deduction, seeing that they are necessary for preparation for the higher degree which "Resident" is expected to take?

* It is understood that payments of this nature are not "grants" in the true sense of the word, but are regarded as made by the hospital in respect of services rendered. On that basis they are liable to income tax. Similarly any sum paid for maintenance is subject to tax in the same way as the E.M.S. living-out allowance. The position as regards the cost of technical books, etc., is not free from doubt. To be allowable such expenses must be incurred "wholly, exclusively, and necessarily in the performance of the duties of the office." If "Resident" establishes the fact that one of the duties required of him is to prepare for the higher degree, the expense should be allowed as a deduction from the salary. The point may well be worth taking to appeal before the District Commissioners of Taxes if the local inspector of taxes is not willing to concede it.

Research Grant

W. T. is in receipt of a research grant to provide for expenses and, to some degree, maintenance. The local tax office regards the grant as assessable to tax.

* The question is governed by Sec. 28 of the Finance Act, 1920. The grant is exempt from tax if W. T. is receiving full-time instruction at a university, college, or other educational establishment. If—as appears probable—W. T. cannot claim to comply with this condition he will be liable to assessment in respect of the grant but should claim to deduct a reasonable amount for the expenses necessarily incurred in the research, the carrying out of which he is required to do under the terms of the grant. He is advised to call (preferably by appointment) at the tax office to explain what expenses he claims, and to raise the question of the tax deductions being made under P.A.Y.E. at present—they are apparently excessive and perhaps made because W. T. has not lodged a statement of income, etc.

LETTERS, NOTES, ETC.

Nomenclature of the Rh Blood Types

Dr. BRYCE R. NISBET (Hon. Sec., Ayrshire Division, B.M.A.) writes: Let me assure Lieut.-Col. G. E. W. Wolstenholme (Nov. 16, p. 753) that the lecture as delivered to the Ayrshire Division by Prof. Cappell was considerably simplified and illustrated by slides and drawings. We were thus able to see and listen and, as evidence that it was much appreciated, as many as eight of the forty-four members who were present took part in the discussion. We, north of the Cheviots, being such large consumers of porridge, like a little "meat" at our gatherings. It is about the only time we can have a surfeit. Whether we shall be able to stand it in the future is a matter of conjecture since oatmeal has been put on points.

Definition of Health

Dr. D. F. TORRENS (Market Rasen) writes: Dr. W. F. Felton (Oct. 19, p. 591) raises the fundamental question. He says "surely complete physical, mental, and social well-being is a god-like state . . ." but he goes on to say that "we can hardly hope to attain [it], let alone claim [it] as our right." He prefers "a balanced state of physical, mental, and social well-being." Neither of these definitions is yet actual in the human race. Each is a statement of an objective to be worked for. There is a vast difference between them. The first is a statement of a belief in a god and that man's goal is to become like God; as Dr. Felton says. The second does not go nearly so far, though it might be pushed a good way in the same direction; it asks only for a balance, and that balance might be established at a very low standard. Also it is man who will set the standard. It is because, in all our social legislation, the ideal expressed and implied is a super-man that the results are disappointing. The best man is not good enough, for though he is immortal he is transitory. Other men with other motives and methods take his place. This is seen in the proposed changes in medicine. Instead of a Ministry of Healing we are to have a huge business organization controlled by scientific analysis and economic theory. But there is nothing to control the controllers. Man is so puffed up (if not yet blown up) by his success (?) in splitting the atom that he has quite lost sight of the Almighty Power which made every atom. Such a mentality will never do good work. No one can who does not know his material. If medicine does not nail its colours to the mast, if it wavers in its loyalty to Christianity, it must become the tool of "scientific research" and the slave of "economic theory."

Ichthyol

Dr. J. AITKEN McEVEN (Barnsley) writes: In his letter (Nov. 23, p. 804) Surg. Lieut. G. B. Hopkins comments on the geological origin of ichthyol as being "the schist . . . regarded by geologists as having originated by fossilization of seabirds' excreta." My recollection (quoting, I believe, Poullsson's *Pharmacology*) is that ichthyol is derived from destructive distillation of a shale, found in the Dolomites, containing the teeth of fossilized fish. I always understood that this fact was responsible for the name of the product (*ichthys* = a fish). While I lay no pretensions to any qualification in geology, I beg leave to doubt the statement that any schist could be the result of fossilization. I stand, however, prepared to be corrected in both statements.

Effects of Penicillin Lozenges

Dr. A. J. COLBY TINGEY (Epsom) writes: Dr. I. G. Cameron (Oct. 26, p. 638) considers it would be of interest if doctors would write of their experiences with these lozenges. It appears possible that in some cases penicillin lozenges may actually lower the patient's resistance to bacterial infection. For example, in June last I was consulted by a patient aged 31 who had a mild form of tonsillitis with a temperature of 99° F. (37.2° C.), and at his request I gave him a prescription for penicillin lozenges. Three days later I received an urgent message from his wife, and found him in bed at home with a temperature of 104° F. (40° C.), and the usual symptoms of acute toxæmia. He was very ill for the next few days, but made a good recovery with sulphonamide treatment. I submit that acute tonsillitis is a general infection, and that to treat the complaint with penicillin lozenges is little better than a placebo. The attitude of the general public to penicillin may best be described by the Latin tag—"Omne ignotum pro magnifico."

Foreign Body in the Duodenum

Mr. D. LIVINGSTONE POW (Wrexham) writes: It is recognized that long objects—e.g., nails—are apt to become arrested in the second or third parts of the duodenum. The following case is of some interest. A female child aged 1 year and 11 months was admitted to the Wrexham and East Denbighshire War Memorial Hospital on Sept. 24, 1946, with a history of having swallowed the buckle of a pram-belt on Aug. 19. The child had been taken immediately

to the Out-patient Department; but, although x-ray examination had demonstrated the foreign body and also the fact that it was remaining in the same place, no step was taken for a time, possibly because the radiologist was inclined to the opinion that the object was not in the stomach or duodenum. (A barium examination of the child was not easy because of struggling.) The child appeared perfectly well throughout the period between ingestion and operation. The latter was performed on Sept. 25. It was difficult, as usual, to locate the buckle, but it was finally detected in the second part of the duodenum. Attempts to manipulate it downwards failed: for a time it could not be persuaded to move upwards. However, eventually it was felt to slip towards the pylorus, and while it was held there an incision was made in the anterior wall of the stomach near the antral area. A finger introduced into the interior of the stomach could feel the buckle presenting at the pyloric ring, but was only with considerable difficulty that the object was finally persuaded sufficiently far through the pylorus to enable my host surgeon—Dr. A. W. Fowler, who was assisting—to grip it with pressure forceps. The cause of the difficulty now became manifest. In the middle of one of the long sides of the rectangular buckle was an interval rather less than one-eighth of an inch (0.32 cm.) in length and in that a fold of duodenal mucosa had been caught. It was disentangled only with some effort, and thereafter the opening of the stomach was closed and the operation terminated. Convalescence was uneventful. The buckle measured one and a quarter inches by five-eighths of an inch (3.18 cm. by 1.60 cm.).

Milk Priority

Dr. ESTHER CARLING writes: A striking instance of wasteful use of milk came to my notice recently. At a small holiday guest house for ex-sanatorium patients (now workers) two pints of milk daily were being delivered for every guest. The housekeeper spoke of her difficulty in "getting rid of it." Such an occurrence suggests that the almost routine issue of two pints daily, sometimes for years, could surely be lessened in these times of stress.

Dr. W. J. LORD (Bath) writes: May I stress one point in letters of Drs. H. E. Collier and G. B. Page (Nov. 16, p. 7): namely, milk priority for old people? Not only, in most cases, their digestive functions inefficient, but they have the added burden of housework and shopping to a much larger extent than before the war. These hardships, again, are often aggravated by arteriosclerosis and high blood pressure.

Pronunciation of Medical Words

Dr. R. L. WYNN (Wallasey) writes: The problems of pronunciation which have been given publicity in your columns arise from the difficulties of assimilation of foreign and dead stems into living structure of a vigorous language, and in their usage may be expected to be variable and sometimes illogical. Many draw attention to another and more serious variety of mispronunciation—the commonly used versions of foreign proper names, mostly surgeons. This, curiously, seems related only to their professional life. An orthopaedic surgeon who correctly recounts that he admires the singing of Gigli the tenor, will later be heard calling for a "giggle" saw. The German "umlaut" suffers horribly, such a name as Böhler is usually ignored, whereas, in its own fashioned form, as in "von Graefe," it commonly acquires separate syllabification of its own, combined this time with a blasphemous disregard for the final "e." Weil and Wassermann are lucky men who generally get a near equivalent of their names. Trendelenburg, however, gets his accent displaced from the first to the second syllable, presumably because the Anglo-Saxon tongue, though accustomed to an accent on the first syllable, gets nervous when the accent of the word is too far off. Another sufferer is Braun, whose English lips brings to mind a popular meat dish rather than the familiar colour represented by his name. Before we embark on what must be purely academic discussion of the pronunciation of words which in their origin are all neologisms, would it not be wise to set our house in order regarding words of whose pronunciation there is no doubt, once due attention is given to them?

Dr. A. R. NELIGAN (Droitwich) writes: Your correspondent Dr. R. O'Rahilly (Nov. 9, p. 711) and other readers may be interested to know that, at a meeting of the International Society of Hydrology held at Buxton last month, an American doctor who read a paper pronounced the "e" of the word "syndrome" throughout.

Dr. MARGARET VIVIAN (Bournemouth) writes: Three of my colleagues have answered my question regarding the pronunciation of the word schizophrenia: two by letter, and one in your current issue. Each one gives a different version: (1) Shy-so; (2) Skitso; and (3) Skyzo. So it appears that we are, as it were, where we were.

Corrigendum

In the leading article on "The Control of Air-borne Infection" (*Journal*, Nov. 30, p. 820) the word "mass" at the end of the twelfth line from the end should read "mess."

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 7 1946

GENERAL MEDICAL COUNCIL

PRESIDENT'S ADDRESS

The 169th session of the General Medical Council was opened on Nov. 26, Sir Herbert Lightfoot Eason presiding. Dr. R. W. Craig took his seat as direct representative for Scotland for the term ending on June 30, 1951. He was introduced by Dr. Sydney Smith.

The President then delivered the following address:

Since our last meeting we have had to deplore the death of Sir Kaye Le Fleming. He was elected as a direct representative of England in November, 1928, and was three times re-elected—in 1933, in 1938, and in June, 1946, a month before he died. He served the Council in many capacities. He was a member of the Public Health Committee from 1929; of the Pharmacopoeia Committee from 1932 to 1938; and in 1939 he was first elected a member of the Penal Cases Committee, on which he served until he died. Members of the Council will, I am sure, deeply regret the passing of one of our most distinguished and useful members. Sir Kaye Le Fleming not only had a wide experience of private practice in every aspect, but served his profession with high distinction as a member of the British Medical Association, in which he held many important offices. No one who has been a colleague of his on the Council will forget his sound common sense, and his peculiar faculty of rising on occasion and putting his finger unerringly on the vital point of a discussion. His charm of manner endeared him to all his colleagues, and I think the Council will feel that they have lost in Sir Kaye Le Fleming an outstanding example of a family physician and friend. We also have to regret the death on Oct. 3 of Sir Walter Langdon-Brown, who was a member of the Council from 1932 to 1937. He was a distinguished member of the Council, and a worthy holder of the historic office of Regius Professor of Physic in the University of Cambridge. We have further to regret the death of Dr. Wardrop Griffith, who represented the University of Leeds on the Council from 1919 to 1928.

We have lost a valued colleague by the retirement from the Council of Dr. Fraser, the direct representative for Scotland, who did not offer himself for re-election in the summer. He served on the Council for five years, and we shall miss his sound advice on disciplinary matters, particularly when they concerned the maintenance of the best standards of conduct in private practice.

We have to welcome in his place Dr. Robert William Craig, whose experience as former Scottish Secretary of the British Medical Association well qualifies him to assist the Council in all their deliberations.

The Curriculum: Visit to America

The Council in May decided that a stage had arrived in the consideration of the draft Recommendations as to the curriculum when it might be desirable to consult some of those concerned with the medical curriculum in Canada and the United States with a view to finding out if they had any views on medical education which might enlighten the Council in their task. Thanks to the generosity of the Nuffield Foundation, who defrayed the cost of transport across the Atlantic, and of the Rockefeller Foundation, who defrayed the cost of living in the New World, this aspiration was fulfilled, and in the middle of September a delegation from the Council consisting of Dr. Bigger, Dr. Brocklehurst, Dr. Campbell, Dr. Cohen, and myself, with the Registrar, crossed the Atlantic and visited the following medical schools: in New York, the Long Island College of Medicine, Cornell University Medical College, New York Uni-

versity College of Medicine, and Columbia University College of Physicians and Surgeons; the University of Chicago; the University of Michigan Medical School, Ann Arbor; in Canada, the Faculties of Medicine in the University of Toronto and in McGill University; the Harvard Medical School in Boston; and the Johns Hopkins University School of Medicine in Baltimore. In addition, the delegation met representatives of the Council on Medical Education and Hospitals of the American Medical Association in Chicago, and of the National Board of Medical Examiners in Philadelphia. From all these bodies the delegates obtained valuable information as to the requirements for medical practice, the content and lay-out of the medical curriculum, and the views of those who would amend the existing regulations. The delegation returned to this country at the end of October, and a preliminary report on the visit will be presented to the Council during this session.

The Council will have to consider the draft Recommendations further at this session in the light of observations made on them by licensing bodies and medical schools, together with an explanatory introduction; but since replies have not been received from a number of bodies and schools, it appears to be impracticable to conclude the consideration of the draft Recommendations on this occasion. It will therefore probably be necessary to have an additional session in February, at which I hope it may be possible to adopt the recommendations in their final form.

It will be remembered that the Council in May approved the draft of a short medical Bill, restricted in its scope to matters which urgently required legislation. Copies of the draft and of an explanatory memorandum were transmitted to the Minister of Health and to the Lord President of the Council on Sept. 21, with a submission that the Bill should be settled by the Government draftsman with a view to its introduction, as settled, into Parliament at the first opportunity. The draft Bill and memorandum have been circulated to members.

A vote of thanks was accorded to the President on the motion of Dr. Sydney Smith, seconded by Dr. J. W. Bone.

WINTER SESSION

Dental Business

The Council considered reports from the Dental Board on two disciplinary cases. One case was that of Ascott William Harris, registered as of John Bright Street, Birmingham, Dentists Act, 1921, whom the Board had found to be associated with or employed by an unregistered person who with his knowledge and/or assent procured or sanctioned the insertion in newspapers of advertisements for the purpose of obtaining patients and to have received patients through a Hospital for Broken Dentures run by the same person. The other case was that of George William Southwood Clark, registered as of Gateshead, Dentist, 1921, who had been convicted at Northumberland Quarter Sessions of breaking and entering a dwelling-house and stealing certain property. Letters were read from both respondents protesting their innocence. The Council instructed the Dental Board to erase from the *Dentists Register* the names of Ascott William Harris and George William Southwood Clark.

The Council restored to the *Dentists Register* the names of Harry Ernest Best and Alfred Horace Myring.

MEDICAL DISCIPLINARY INQUIRIES

Cases Adjourned from Previous Sessions

The Council considered the case of Anthony John Watkins, registered as of Newport, Mon., against whom it had been found that in June, 1944, he was convicted at the Central Criminal

Court of unlawfully using an instrument and was bound over for two years. The Council also had postponed judgment for two years. Dr. Watkin now produced three testimonials from members of the medical profession as to his exemplary conduct in the interval. The Council, in view of this satisfactory evidence, did not see fit to erase his name, and closed the case.

The Council next considered the case of Graham George Robertson, registered as of Mariners Lane, Tynemouth, against whom the Council had found, in 1944, that in 1942 he had been judged by a court-martial at Quetta to have been drunk on active service and had been sentenced to be dismissed from the Army, and that in 1943 he had been convicted at Newcastle of driving a car while under the influence of drink. The Council had postponed its judgment on the finding, and subsequently at two sessions had granted further postponements owing to Dr. Robertson's state of health. Dr. Robertson now appeared, but the Council was not satisfied with the evidence tendered on his behalf and with his present condition, and instructed the Registrar to erase his name from the *Medical Register*.

The next case was that of John Corboy, registered as of Tycoch, Swansea, against whom it had been found that he had been twice convicted in 1945 at Salford Police Court of driving or being in charge of a car while under the influence of drink. The Council had postponed judgment for one year. Dr. Corboy now attended and produced two testimonials from medical colleagues. The Council, in view of this satisfactory evidence, did not see fit to erase his name.

Convictions for Misdemeanour and Charges in Respect of Patients

The Council proceeded to consider the case of William Francis Hirsch Coulthard, registered as of Aspatria, Carlisle, who appeared on the charge that in March, 1946, at Carlisle, he had been convicted of being drunk and disorderly, and in April, 1946, at Cockermouth, of being drunk in charge of a car (on which occasion he was fined £50). He was also charged with using obscene language and being under the influence of drink while attending a patient in 1942 on the birth of her child; with similar behaviour on various occasions between 1943 and 1946 when visiting another patient, on one of which occasions he was alleged to have struck the patient; with having given a certificate in October, 1945, without having seen or examined the patient at the time; and, finally, with having obtained from a firm of chemists supplies of "myocrisin" by falsely representing that the drug would be administered to one of his patients, whereas in fact certain of the supplies were not so administered.

Dr. Coulthard attended with Mr. H. D. Peacock, counsel, instructed by Le Brasseur and Oakley, solicitors, on behalf of the London and Counties Medical Protection Society. Members of the Council who were members of that Society withdrew and took no part in the proceedings.

Mr. S. G. Howard, counsel, instructed by Waterhouse and Co., solicitors to the Council, attended to present the facts of the case. Mr. Howard asked permission to amend the charges by adding four other convictions: in 1943 at Keswick, of failing to immobilize a car during the hours of darkness; in 1944 at Carlisle, of wrongful use of motor fuel; and in 1945 at Wigton, of two offences on different dates, both concerned with the use of obscene or abusive language. The Council ruled out the first of these convictions as not falling within its province. The others were added to the charge.

Mr. Howard explained the circumstances of the convictions. He then dealt with the first of the charges relating to patients. Dr. Coulthard was summoned to attend a Mrs. Wright, of Aspatria, on the birth of her child, and, according to her story, when he came he was under the influence of drink and used obscene language. The next charge concerned a Mr. Aitken, a patient, who had since died. It was alleged that at various times he had called at the Aitkens' house when he was under the influence of drink, had used bad language, and on one occasion had assaulted the patient, making his nose bleed. "If the evidence bears out these facts," said Mr. Howard, "the Council may have difficulty in finding language temperate enough to describe conduct of this kind." The other two charges were of a different character. The husband of Mrs. Wright had contracted malaria in Burma, and, having an attack when home on leave, it was alleged that his wife had obtained a certificate from the doctor

stating that he had malaria and was unfit to travel, though the doctor had not seen or examined the patient. The last charge related to wrongfully obtaining a drug. A Mrs. Arnott had suffered from rheumatoid arthritis, and Dr. Coulthard had attended her under a county council scheme for domiciliary medical relief and had prescribed "myocrisin" and had injected the drug, but later failed to attend for this purpose, though on two occasions he had obtained supplies of the drug.

Mrs. Eleanor Mary Wright gave evidence that when Dr. Coulthard attended her on the birth of her child he had been drinking, and he used bad language, though the only word she could recall was "Hell!" With regard to the certificate stating that her husband was suffering from malaria she admitted that her husband had been to see the doctor at the beginning of his attack a week previously. Mr. Wright, the husband, gave contradictory evidence. He agreed that, about a week before his wife visited the doctor and obtained the certificate, he himself went to see the doctor, who took his pulse and temperature. The President said that a good deal turned upon the form of the words in the certificate, but the certificate had gone to the military authorities and could not be produced.

Mrs. Sarah Aitken gave evidence that once or twice when Dr. Coulthard attended her husband he was drunk. She judged this by his attitude and language. Asked what the language was she said she would not like to repeat it, but she was persuaded to write down the words for the benefit of the Council. On the occasion of one visit he struck her husband. She also alleged that during the week preceding her husband's death, though Dr. Coulthard was repeatedly sent for, he did not come. Asked why she and her husband continued to employ Dr. Coulthard despite these alleged acts, which extended from August, 1944 to March, 1946, she said that he was her husband's panel doctor. No complaint was made to the Insurance Committee. Another witness, a Mrs. Anderson, testified that she had seen Dr. Coulthard the worse for drink at Mrs. Aitken's house, but on being pressed she could not remember the dates or even the month.

With regard to the last charge, that of obtaining "myocrisin" under alleged false representations, it was stated that four ampoules were supplied by the chemists in January, 1946, and four in April, 1946, on Dr. Coulthard's requisition on behalf of one of his patients, a Mrs. Arnott, but no part of these supplies was administered to her. In a declaration Mrs. Arnott stated that in October, 1945, she and her husband became entitled to free medical service under the Public Assistance Committee, and continued to have Dr. Coulthard, who had been their doctor for the previous nine years. She had suffered from rheumatoid arthritis, and for about five years she had been getting "myocrisin" for injections and paying Dr. Coulthard for obtaining and administering the drug. The last injection she had had was in June, 1945.

In evidence on his own behalf Dr. Coulthard admitted the convictions, but denied that on the first occasion, though there was an altercation, he was the worse for drink. With regard to the second conviction, of being drunk in charge of a car, he said that he was "run down" at the time and had had a certain amount to drink. Since that occasion he had left off drinking entirely, and he gave assurances for the future. Concerning the charges of using bad language in the presence of patients, he gave a total denial. The woman whom he had attended in childbirth in 1942, on which occasion, it was said, he was under the influence of drink and used obscene language, had been attended by him on several occasions since, and so far as he knew was still his patient. Concerning the certificate given to this patient's husband, he said that he saw him a few days before he gave the certificate to his wife, and he had no doubt that a malarial attack was beginning; he had treated him several times since. He gave a total denial of the charge in respect of the Aitkens, and said that he had never struck the male patient. With regard to Mrs. Arnott, she had been a patient of his for some years. Her husband, an old-age pensioner, was in receipt of a supplementary pension, and in these cases certain drugs were obtainable without charge from the social welfare department of the county council. He prescribed "myocrisin" and for this purpose filled in a form addressed to the social welfare department for a number of ampoules in respect of the following period. At this time, owing to a difference between himself and her stepson, Mrs. Arnott changed

her doctor and did not have the "myocrisin." Through an error he omitted to notify the social welfare department that eight ampoules were unused and were still in his possession. He had not made any false representation, and when he asked for the supply he intended to administer it to her and would have done so but for the fact that she had changed her doctor.

Miss M. McMurren, a registered midwife, of Aspatria, testified that it was she who sent for Dr. Coulthard in the case of Mrs. Wright. When he arrived he was certainly not under the influence of drink, nor did he use bad language, but on that and the following day he made all necessary arrangements for the patient. In the course of frequent professional association with Dr. Coulthard over a period of nine years she had never known him the worse for drink, or use bad language, or be other than most attentive to his patients.

After Mr. Peacock had addressed the Council on the respondent's behalf, and Mr. Howard had reminded the Council of the points brought out in the evidence for the complaint, the Council deliberated *in camera* and found the convictions proved; also the charges in respect of the Aitkens, that Dr. Coulthard had used obscene language and had been under the influence of drink while visiting them in a professional capacity, and on one occasion had assaulted Mr. Aitken; and the charge in respect of Mrs. Arnott, that he had wrongly represented concerning two batches of drugs that they were for administration to one of his patients. The Council dismissed the charges relating to the Wrights. The President stated:

"The convictions and the facts which have been proved against you are discreditable to you and to your profession and indicate habits which may be dangerous to your patients. But in view of the assurances that you have given to the Council at this hearing as to your abstinence from alcohol in the past and your assurances as to the future, the Council have decided to postpone judgment on your case for a period of two years. But they will require that you shall appear before them at the session in November next and produce testimonials from your professional brethren and other persons of standing as to your behaviour and habits in the interval."

Convictions

The Council proceeded to consider the case of Reuben Denny, registered as of Twyford Avenue, Acton, who had been convicted on May 20, 1946, at Marlborough Street Police Court of driving a motor-car while under the influence of drink, had been fined £50 and had his licence suspended for twelve months. Dr. Denny attended, and while admitting the conviction made a statement in extenuation. He had been ill during the first six months of this year, and in 1943 was invalided home from Gibraltar with head injuries.

The Council postponed judgment for one year.

The Council considered the case of Ethel Grundy Toward, registered as of Birtley, Co. Durham, who appeared on the charge that she had been convicted at Gateshead in September, 1945, and in February, 1946, of driving a motor-car while under the influence of drink. Dr. Toward, who was represented by Mr. H. D. Peacock, counsel, instructed by Le Brasseur and Oakley, solicitors, on behalf of the London and Counties Medical Protection Society, gave evidence that at the time of these occurrences she was helping her husband to carry on a busy practice of 2,700 panel patients, 2,500 club patients, and private patients in addition, and was also having to do the whole work of the household without assistance. She had afterwards gone to Crichton Royal, Dumfries, for a course of treatment, from which she had greatly benefited. Dr. Walter Toward, the husband of the respondent, gave confirmatory evidence.

The Council found the convictions proved, but did not see fit to direct the Registrar to erase Dr. Toward's name.

Restorations

The President announced that the following had been restored to the *Medical Register* after penal erasure: James Jackson Brown, Erich Hohenberg, Arthur Patrick Kennedy, Matthew Morgan-Daley, Brendan O'Carroll, Archibald Walker.

Reports of Committees

Dr. Campbell presented the report of the Pharmacopoeia Committee which embodied a report of the British Pharmacopoeia Commission. All the text of the new *British Pharma-*

copoeia had been sent to the printer, but it was not yet possible to announce the date of publication.

Inspection of Qualifying Examinations

Prof. R. J. Brocklehurst, chairman of the joint meetings of the Education and Examination Committees which have been considering the reform of the medical curriculum and the inspection of qualifying examinations, presented a report on the latter subject. The talks on the curriculum were not yet completed; it is hoped to report on them at the extra February session of the Council. With regard to the inspectors' reports, Prof. Brocklehurst said that these extended over the period 1942 to 1946, and the task of reinspection had now been completed. It had not been an easy task in view of the emergencies of wartime. Despite the possible effects of war conditions on the standards of the qualifying examinations, the inspectors were satisfied that the character of the examinations had not deteriorated. The inspectors first reported that, with three exceptions, the examinations which they had inspected were sufficient, and on reinspection of these three excepted examinations it was found that they also had now come up to the sufficiency standard. It had been felt that, in certain examinations the examiners spent rather a long time on the examination of the better type of candidates, and in some cases borderline candidates received rather less than adequate attention. The committees felt the need of reaffirming the paramount importance of ensuring that no candidate should be allowed to pass the qualifying examination, and thereby obtain the right to registration, unless he possessed the knowledge and skill requisite to the efficient practice of medicine, surgery, and midwifery.

An important point was the taking into account of the candidate's record at the time of the examination. It was reported that at a number of examinations in medicine such records were not taken into account, and the committees wished to draw the attention of licensing bodies to the Council's previous recommendation in this respect, and to express the hope that the assistance which could be obtained, especially in the case of borderline candidates, by the record of the work done during their course of study would be appreciated by the examiners.

Another question dealt with was the possibility of establishing a panel of examiners by the Council, from which panel examiners could be selected for the various bodies. This was carefully considered by the committees, but it was felt that the circumstances were not such as to justify the adoption of the proposal, which would be felt to impose a serious restriction on the freedom of choice of the licensing body.

The report was approved by the Council without discussion and is to be circulated to the licensing bodies for their information.

Dr. N. E. Waterfield was elected to fill a vacancy on the Penal Cases Committee caused by the death of Sir Kaye Le Fleming.

The Council concluded its business with a vote of thanks to its President, proposed by Dr. J. W. Bone and seconded by Dr. J. P. Hedley.

INSURANCE ACTS COMMITTEE CONTRIBUTIONS FOR DEFENCE FUND

The first ordinary meeting of the new session of the Insurance Acts Committee was held on Nov. 21. Dr. E. A. Gregg was unanimously re-elected to the chair. The committee agreed that an appropriate letter be sent to Dr. Lewis Lilley, who had been a member for very many years, on his retiring from membership.

The chairman gave a report on the opening of conversations with officers of the Ministry of Health on the question of the capitation fee. He said that the practitioners' case had been put forward in general terms, but also with a fair amount of detail, and a further meeting would be held on Dec. 5. There was no reason to be dissatisfied with the conversations so far. To some members who expressed surprise at the delay at reaching a conclusion on what was a matter of arithmetic it was pointed out that the Spens Committee Report had mentioned as a relevant consideration not only the difference in money values between 1938 and 1945 but the increases in incomes of members of other

professions. A report by a leading economist—an unimpeachable authority, as the Ministry itself would recognize—had been presented by the committee to the Ministry, and in this report it was stated that the level of prices for professional families in 1945 was 145 to 150% of that obtaining in 1938.

Increase of Levy

In discussion on a report of the National Insurance Defence Trust Dr. S. Wand urged that the trustees should consider whether the amount of voluntary levy should not at this juncture be increased from 1d. for each insured person to 4d. Dr. W. D. Steel supported this proposal and said that the Trust had every right to expect an allocation from the additional 2s. which practitioners were obtaining, on account, this year. Dr. F. A. Roper said that Exeter had unanimously resolved to increase the voluntary levy to 6d. The resolution that panel committees be communicated with and asked forthwith to increase their contributions was carried without dissent.

Various proposals were put forward as to the amount and method by which the voluntary levy should be increased. Members were asked to indicate whether in their own panel committee there was a small statutory fund from which the committee met its expenses, the practitioners signing a document for the deduction of a certain amount from their quarterly cheque for the defence fund, or whether there was a voluntary fund which served for both expenses and contributions to the fund. The majority indicated that the former method obtained in their areas; thus any decision as to a larger amount would require a new signed undertaking from each practitioner. The importance of the filling up of their quotas by panel committees which have not yet contributed the full amount on the existing undertaking was stressed. Difficulty was experienced in arriving at an unambiguous formula for the amount and method of the increased levy, and further consideration of the matter was deferred until the next meeting.

A letter was read from one panel committee stating that it had deferred the question of making increased contributions until it had learned how the unused money to the credit of the fund would be disposed of when national health insurance came to an end. The chairman said he could only suggest that it would be perfectly in order for the trust, under its constitution, to continue to function in whatever service was substituted for national health insurance, and sums such as had never been required before might be necessary. It was agreed that a plain statement of the purposes and uses of the fund should be prepared and sent to every panel committee.

A Standard Formulary

Dr. F. Gray reported that the joint committee of the B.M.A. and the Pharmaceutical Society had referred for consideration to the Insurance Acts Committee a resolution that consideration be given to the need for a standard formulary and that it be based on the formulary section of the *British Pharmaceutical Codex* and compiled by a joint committee of the two professions. The I.A.C. endorsed these proposals. The chairman said it was not suggested that the formulary should consist merely of formulae taken from the codex: there would have to be very considerable additions.

The committee considered the instruction of the Annual Conference that immediate steps be taken to secure the heavier weighting of mileage. Dr. J. A. Ireland said that owing to long distances and difficulty of access the rural practitioners of his area were strongly of opinion that the weighting of mileage should take place on a much higher scale. The chairman said that the question of mileage would be taken into account in the conversations concerning the capitation fee. A resolution of the Conference concerning the inadequacy of the present dispensing capitation fee was referred to the Rural Practitioners Subcommittee.

A reply was reported from the Ministry to suggestions which the committee had made concerning postgraduate courses for insurance practitioners. The Ministry stated that it was willing to consider special cases brought to its notice where a doctor had been doing a reasonable amount of insurance work although technically he had failed to satisfy the condition as to the size of list which would entitle him to admission to the refresher courses.

HEARD AT HEADQUARTERS

Nearly Unanimous

Although for the time being the question of resignation from the panel is in abeyance while conversations are proceeding over the insurance capitation fee, it is useful to have on record the returns of reports from Insurance Committee areas. A but 10 of the 190 areas have now reported. In these 10 the number of insurance practitioners is some 1,500. One of the areas, by the way, is the Isles of Scilly, where, so it was stated at the meeting of the Insurance Acts Committee, there is only one insurance practitioner, who, presumably because of his inability to get a seconder, could not send forward a resolution. In the 180 areas reporting, the proportion of practitioners who favoured the I.A.C. recommendation was 94.7% of those attending the meetings or replying to the personal and postal canvass; the proportion not in favour was 2.6%, and a similar proportion abstained from voting or gave indecisive replies. As some of these last can now be presumed to have come round to decision it is a conservative estimate to state that over 95% are behind the I.A.C. in the line it has taken. This is about as solid a demonstration as any democratic vote can be—far more impressive than the card vote at a trade union meeting while the writer attended the other day, when a resolution was carried by 300,000 to none.

Doctors and Patent Medicines

The Hunterian Society staged a good debate at the Apothecaries' Hall recently on the motion: That the uncontrolled advertising of patent medicines is a menace to the public. The motion was carried, of course—with eight dissentients in a meeting of about 100. The chief advocate on each side was a layman—Mr. Hugh Linstead, M.P., the secretary of the Pharmaceutical Society, and Mr. Arthur Mortimer, director of a company which controls a well-known proprietary remedy. One of the points made in the debate was that doctors ought to get up and bleat proprietary medicine manufacturers, for if doctors had to do with all the people who go round to get something from the chemist to relieve an ache or pain their surgeries would become impossible. The doctors would be seeing again all those people whom they hoped they had seen for the last time. What would they do? Rubber-stamp the lot, or go through them as conscientiously as they do the patients who at present come for hot-water bottles, priority milk, and corsets?

The amount spent on patent medicines called forth some widely varying estimates. One doctor in the discussion said that ninety millions a year was spent on advertising the lot, but Mr. Mortimer declared that the figure was nothing like that. The last published figure, for 1938, was £4,835,000 for the advertising of all these preparations, including tonics, wines, veterinary medicines, and rupture appliances, and the advertising accounted for no more than 8% of the total advertising space in newspapers. But he admitted that this related only to advertising in the national newspapers and took no account of advertising by posters on railways and elsewhere or advertising by correspondence.

Harvest Ahead

One suggestion made at the Hunterian Society debate sent us back to an old volume of *Punch*, for 1912, which depicted a depressed Mr. Lloyd George contemplating his National Health Insurance Bill, while in the street below there is a procession of doctors bearing a banner, "Doctors Demand a Living Wage." With the Chancellor, however, is a figure representing patent medicines, with the legend on his front, "Magic cures; the only successful remedy for . . ."—a score of complaints—who says: "Never mind, dear fellow, I will stand by you—to the death." The advent of national health insurance did not, apparently, diminish the demand for patent medicines, and now, according to the anticipations of the Hunterian speakers, the coming of a National Health Service will make patent medicines flourish more than ever. One of the speakers—Dr. G. H. Day, who prophesied that the sales would be doubled or trebled—gave psychological reasons for his forecast. He pointed out that there is an ineradicable conviction in the human mind

that what is not directly paid for is of no value. "Nothing for nothing; very little for a penny." The sufferer from any ill feels the necessity for some propitiatory sacrifice; perhaps it is connected more or less remotely with a sense of sin. He may get satisfaction by paying the doctor's fee, but with "free for all" medical treatment patent medicines will be the only altar upon which his sacrifices can be piled.

Surgeons up in Arms

There was no doubt about the feeling at the recent special meeting of Fellows of the Royal College of Surgeons, which was called by requisition to consider the situation under the new Act. Although no vote was taken, only two of the ten speakers expressed themselves in favour of entering upon discussions concerning regulations, and to judge from the volume of assent and dissent which followed the oratory that propo-

tion more or less represented the disposition of opinions held by the audience of 150. The statement of the President that as a corporate body the Council had answered "Yes" to the question whether it desired the Negotiating Committee to enter into discussions with the Minister obviously took many Fellows by surprise, but he immediately made it clear that this decision was binding upon no individual, and he agreed at once—indeed it was his own suggestion—that the communiqué given to the Press about the meeting should state that it was agreed that the College should act in conformity with the general feeling of the profession (presumably in accordance with the result of the plebiscite). It must be a long time since there was a meeting at Lincoln's Inn Fields so animated and prolonged (it lasted 24 hours). In years gone by the annual meetings of Fellows and Members often failed to muster the quorum of thirty.

MEDICAL WAR RELIEF FUND

SIXTH ANNUAL REPORT

This report covers the year from Sept. 1, 1945, to Aug. 31, 1946. During this period the applications for assistance from the fund, which had become progressively more frequent in the two previous years, continued to increase in number. The number of awards made by the Distribution Subcommittee during the year is 81, the total amount of these awards being £18,016. The corresponding figures for the year 1944-5 are 56 and £11,344. The total amount distributed since the inauguration of the fund is £52,236.

As had been expected, a large majority of the applicants during the past year were ex-Service doctors who, on returning to civil life, were faced with financial difficulties resulting from their war service. The typical case is that of the general practitioner whose single-handed practice declined seriously during his absence and who needs temporary assistance to tide him over the difficult initial period of resettlement. The other

miscellaneous applications received during the year included ten from widows of doctors who gave their lives in the war.

The audited statement of accounts for the year is appended to this report. The contributions received since the committee of the fund published the second appeal for subscriptions at the beginning of December, 1945, amount to approximately £22,000. This is much less than the sum which had been estimated to be necessary, but on the other hand the demands made on the fund during what has been the "peak" year have also fallen short of expectation; and the new subscription income, although it has not added greatly to the fund's resources for the future, has exceeded the year's relatively heavy expenditure.

The special subcommittee concerned with the provision of medical books for medical prisoners of war was not re-appointed last year, the need for its services having come to an end. The subscriptions specially earmarked for this purpose amounted to approximately £217. The committee has now fully discharged its financial obligations to the Educational

Examined with the books and vouchers and found correct.

J. Frederick's Place,
Old Jewry,
London, E.C.2.

Oct. 10, 1946.

Books Section of the Red Cross and St. John Joint Organization, which gave invaluable assistance in the purchase and dispatch of the books, and a balance of approximately £67 remains unspent. This sum has been transferred from the prisoners-of-war account to the general account in accordance with the arrangement proposed when the appeal for specially earmarked subscriptions was published.

Future needs are not easy to estimate, but it is to be expected that, as demobilization proceeds, the fund will continue to receive appeals from returning Service doctors who have legitimate claims for a substantial measure of help. It seems probable also that the assistance given to widows, usually for the education of young children, will have to be continued for some considerable time to come. Therefore, although the present financial position is not such as to cause immediate anxiety, the committee would again urge the claims of the fund on those members of the profession who have not yet responded to last year's appeal. Cheques should be made payable to the Medical War Relief Fund, and addressed to the Honorary Treasurer of the Fund at B.M.A. House, Tavistock Square, W.C.1. To the many generous supporters of the fund who have sent further contributions in recent months the committee wishes to express grateful thanks.

Once again it is the pleasant duty of the committee to record its great indebtedness to the Royal Medical Benevolent Fund and its secretary, Mr. Pennefather, for their invaluable assistance, particularly in administering the awards in cases in which the payments are made by instalments over a period of years. Their knowledge and experience have been of great advantage in cases of this kind, of which there have been no fewer than 50 since 1941. Thanks are due also to the British Medical Association for continuing to provide accommodation for meetings and for much assistance given in other ways, especially in connexion with the second appeal for subscriptions. Finally, the committee acknowledges with gratitude the valuable help received from Messrs. Price, Waterhouse, and Co., who have again given their generous services as honorary auditors.

H. GUY DAIN,
Chairman.

Correspondence

The "Closed Shop"

SIR,—Dr. F. R. Ellis (*Supplement*, Nov. 23, p. 138) raises a most important question. By a coincidence it happens that a similar attempt to that described by Dr. Ellis has just been made to impose the "closed shop" principle upon the teaching profession. I have repeatedly pointed out the analogy which exists between the measures taken under the Education Act and those threatened by the N.H.S. Act, and this new example is particularly significant. On Nov. 5 the education office of the Gateshead Council issued a circular which declared that, in response to a demand from the industrial section of the Gateshead Labour Party and Trades Council, the Gateshead Town Council now made it a condition of employment for all its employees that they should become members of an appropriate trade union—and employees were required to return forms signed as signifying acceptance of this requirement within three days of the issue of the circular. The immediate reaction to this circular was a meeting of the N.E. Federation of School Masters (Nov. 9, 1946), when a resolution was passed unanimously recommending their Gateshead colleagues that they should not complete the form; and 500 teachers have, up to date, rejected this demand.

I drew the attention of the Minister of Education to this position (*Hansard*, Nov. 21, 1946) and enclose a copy of both question and answer.

Sir Ernest Graham-Little.—To ask the Minister of Education if she is aware that the Gateshead Council are demanding that teachers employed by them shall belong to trade unions as a condition of engagement; that 500 teachers have rejected this demand; whether the action taken by the council is authorized by her; and if she will give directions in this matter.

Miss Ellen Wilkinson.—The answers to the first two parts of the question are in the affirmative and the answer to the third part is in the negative. As regards the fourth part, it is the policy of the

Government to leave the question of conditions of employment to be settled between the parties concerned, and there does not at present seem to be any occasion for my intervention.

It is to be noted that the Minister of Education, following the example of the Minister of Labour in his attitude to the "closed shop," decides to preserve a neutrality unbenevolent to the teachers.

It is notorious that there is widespread dissatisfaction in both the medical and teaching professions with the current or threatened conditions of service, and there is every prospect that both the Education Act, 1944, and the National Health Service Act, 1946, will ultimately founder on this particular rock of the refusal of members of both those professions to take service under the terms imposed upon them. It seems therefore peculiarly inappropriate at this moment to add yet another condition which cannot but accentuate that scarcity.—I am, etc.,

House of Commons.

E. GRAHAM-LITTLE.

The "Closed Shop" at Willesden

SIR,—The latest threat of the "closed shop" is against the nursing staff of the Willesden Municipal Hospital. It is to be hoped that we shall give them, and any other nurses elsewhere in danger of victimization, all the help and encouragement in our power.

The danger to the dearest traditions of medicine must surely be apparent to those who canvass an affirmative reply to the B.M.A. plebiscite. Many of our senior representatives hardly seem to be aware of the irretrievable loss of freedom and enterprise that will be killed insidiously if the present Act is ever put into effect. Medicine must never be tied to one party or associated with medico-political organizations. It is but a short step to the "closed shop"; preferment will be a political reward, an appointment will go to the man who is associated with the party's administration. My God! What have we been fighting for?—I am, etc.,

Little Aston.

J. B. W. HAYWARD.

SIR,—I wonder if it is generally known by the profession that the Willesden Council's decision that all their employees must join a trade union or be given notice applies to doctors. I know one doctor who applied for a post with them and received written intimation that this was a condition of employment. It would be interesting if we knew what union the doctor was supposed to join and whether he would be bound to come out on strike when necessary.

Personally I might be persuaded to join a union if by doing I avoided losing my job, but I am glad to see that the Willesden nurses are not adopting such a pusillanimous attitude as myself. Yet if I did so I cannot see myself going on strike; but if I didn't, then I should either precipitate a further strike or get chucked out of the union.

Perhaps the Willesden Council are prepared to clarify the situation with regard to doctors and define exactly why they must join a union and what regulations they will be bound by should they be compelled to do so.—I am, etc.,

Dartford, Kent.

J. MACKAY CRAWFORD.

Medical Unemployment and Public Appointments

SIR,—Another of the "Unemployed" (Nov. 23, p. 138) is surely striking a wrong note when he writes complaining that local authorities do not give preference to ex-Service holders of the D.P.H. Those who served their country at home did so through no choice of their own: the destinies of all were in the hands of Ministries and medical war committees, and the Government of Northern Ireland is as unfair in discriminating against the wartime civilian as other authorities may be in discriminating against the ex-officer. We were all in it together and proud to be, so let us have no disputes between one section of the profession and another.

What is wrong, and always has been wrong, is the way doctors are appointed and promoted in the public health service. If this were done by informed and unbiased persons who could give due weight to professional qualifications and to experience both in the Forces and in civil appointments, there would be no occasion for the recriminations of "Another of the Unemployed" or for the dissatisfaction of many who are already in the service.—I am, etc.,

Sussex.

Harper, P. Hogg, R. M. Lang, C. H. B. Lawfield, T. Lloyd, J. L. McDougall, N. McDougall, I. A. McGregor, Lyon, D. L. Mackay, G. L. Mackay, W. G. McIntosh, H. A. B. Mackay, S. J. R. Macoun, A. Marshall, J. Mathieson, M. B. Matthews, R. Merryweather, A. A. Mudie, J. Oldfield, R. H. Park, Ramsay, W. A. T. Robb, N. V. Sapier, M. Schwartz, I. S. R. Sinclair, F. J. Spencer, N. B. Sprague, C. P. Tanner, D. S. Thomson, Thomson, P. L. Watts, H. Williams, M. Wood, W. Wood, I. Wrenab, and H. Bourne.

ROYAL AIR FORCE

ROYAL AIR FORCE VOLUNTEER RESERVE

Flying Officers J. N. C. Cooke, A. M. Dawson, H. F. W. Fry, and D. McGrath to be War Subs. Fl.-Lieuts.

DENTAL BRANCH

W. D. Clarkson-Webb, M.R.C.S., L.R.C.P., to be Flying Officer (mergency).

WOMEN'S FORCES

EMPLOYED WITH THE MEDICAL BRANCH OF THE R.A.F.

Fl.-Lieut. M. Calvert has resigned her commission, retaining the rank of Squad-Ldr.
Fl.-Lieuts. P. E. Williams and D. R. B. Sullivan have resigned their commissions, retaining their rank.
Elizabeth M. I. Milne to be Flying Officer (Emergency).

INDIAN MEDICAL SERVICE

Major-Gen. Sir J. B. Hance, K.C.I.E., O.B.E., K.H.P., has been promoted to the local rank of Lieut.-Gen., while holding the appointment of Medical Adviser to the Secretary of State for India and President of the India Office Medical Board.
Major-Gen. R. Hay, C.I.E., I.M.S., has been granted the local rank of Lieut.-Gen., while holding the appointment of D.G.I.M.S.
Lieut.-Col. D. N. Bhaduri has retired and has been granted the honorary rank of Col.
Lieut.-Col. J. Rodger, O.B.E., M.C., to be Col.
Lieut.-Cols. C. S. V. Ramanan and L. G. Pearson have retired.
Majors K. F. Alford, S. C. Bakhle and P. J. Kelly to be Lieut.-Cols.
Majors R. De Solderhoff and J. G. Durning have retired.
Majors S. C. Colbeck and B. M. Wheeler have retired, receiving gratuity.
Capt. R. B. Davis, D.S.O., W. M. Wilson, W. A. Hopkins, L. V. Iam, F. M. Byrn, J. W. R. Sarkies, T. Donness, and W. Laurie to be Majors.

Capt. A. M. Best has retired, receiving a gratuity.
The notification regarding the retirement of Capt. A. C. S. Mann in a *London Gazette*, dated June 28, is cancelled.

EMERGENCY COMMISSIONS

Major J. Yu-Chieh Hsu has relinquished his commission and has been granted the honorary rank of Major.
Capt. D. C. Logan, J. M. Murray, G. McCracken, E. L. Jones, and E. D. MacWorth to be Majors.
Capt. G. A. Grahame has retired, receiving a gratuity.

COLONIAL MEDICAL SERVICE

The following recent appointments have been announced: D. Foskett, M.B., Medical Officer, Kenya; F. R. T. Hollins, M.B., B.Ch., Medical Officer, Grade II, Fiji; T. K. Howat, M.B., Ch.B., G. A. Owen, M.B., B.S., H. B. L. Russell, M.R.C.P., Medical Officers, Gold Coast; C. C. Langford, M.B., B.Ch., Medical Officer, Uganda; B. M. Nicol, M.B., Ch.B., Medical Officer, Nigeria; W. O. Petrie, M.B., Ch.B., Medical Officer, Nyasaland; M. T. Read, M.R.C.S., L.R.C.P., Medical Officer, Malaya; W. L. Robinson, M.B., B.Ch., Resident Surgeon, Windward Islands; A. B. Da Costa, M.B., Ch.B., District Medical Officer, St. Vincent, Windward Islands; E. F. B. Forster, M.B., Ch.B., African Medical Officer, Gambia; D. E. Freeman, M.B., B.Ch., Medical Officer, Grade II, British Solomon Islands Protectorate; Z. C. Holub, M.D., Medical Officer, Aden; M. A. Lambert, M.B., Ch.B., Medical Officer, Leeward Islands; A. D. McShine, C. H. Merry, M.R.C.S., L.R.C.P., and R. K. Richardson, L.R.C.P.&S., Medical Officers, Grade C, Trinidad; P. A. M. Van de Linde, M.B., B.S., Medical Officer, Hong Kong; P. C. Cosgrove, M.B., B.Ch., D.T.M.&H., Specialist (Physician) Sierra Leone; E. J. Foley, M.B., Ch.B., D.P.M., Specialist (Psychiatrist) Tanganyika; P. W. Hutton, M.B., B.Ch., D.T.M.&H., Physician Specialist, Uganda; R. B. S. Smith, M.B., B.S., D.T.M., Senior Medical Officer, Northern Rhodesia; T. M. Small, L.R.C.P.&S., D.P.H., Medical Officer of Health, Grade B, Trinidad.

Association Notices

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows: an Ernest Hart Memorial Scholarship, of the value of £200, a Walter Dixon Scholarship of the value of £200 and four Research Scholarships, each of the value of £150. These Scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State Medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession. Each Scholarship is tenable for nine months, commencing on Feb. 1, 1947. A Scholar may be re-appointed for not more than two additional terms. A Scholar is not necessarily required to devote the whole of his or her time to the work of the research, but may hold a junior appointment at a university, medical school, or hospital, provided the duties of such appointments do not interfere with his or her work as a Scholar.

Conditions of Award, Applications

Applications for Scholarships must be made not later than Saturday, Dec. 28, 1946, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants are required to furnish the names of three referees who are competent to speak as to their capacity for the research contemplated.

GROUP OF DERMATOLOGY

A meeting of the Group of Dermatology, to which all members of the Group are invited, will be held at B.M.A. House on Wednesday, Dec. 18, at 2 p.m.

Members of the Group are invited to forward to the Secretary, B.M.A. House, Tavistock Square, London, W.C.1, suggestions or recommendations for consideration by the meeting.

(Sgd.) C. Hill,
Secretary.

Diary of Central Meetings

11. Wed. Council, 12 noon.

Branch and Division Meetings to be Held

COVENTRY DIVISION.—At Coventry and Warwickshire Hospital, Tuesday, Dec. 10, 8.30 p.m. General meeting. Dr. Robert Forbes: The G.M.C.—Hitherto and Henceforth.

GREENWICH AND DEPTFORD DIVISION.—At Miller General Hospital, Greenwich, Wednesday, Dec. 11, 8.30 p.m. Mr. Mortimer Reddington: Maternity Problems.

PADDINGTON DIVISION.—At Inoculation Department, St. Mary's Hospital, W., Thursday, Dec. 19, 8.30 p.m. Sir Alexander Fleming, F.R.S.: Penicillin in General Practice. Members of other Divisions are invited to attend.

RICHMOND DIVISION.—At Royal Hospital, Richmond, Friday, Dec. 13, 9 p.m. Dr. Reginald Lightwood: Paediatrics.

WAKEFIELD, PONTEFRAC, AND CASTLEFORD DIVISION.—At Clayton Hospital, Wakefield, Thursday, Dec. 12, 8.15 p.m. Mr. D. W. Currie: Dysmenorrhoea.

Meetings of Branches and Divisions

BATH DIVISION

At a well-attended meeting of the Bath Division held on Nov. 22, with Dr. G. D. Steven in the chair, the following resolution was passed:

"That this meeting strongly urges the Council to recommend to the Negotiating Committee that if, as a result of the analysis of the plebiscite, it is found that a sufficient majority of the general practitioner group votes against entering into discussions with the Minister on the regulations, the Negotiating Committee should refuse to discuss regulations applicable to the General Practitioner Service.

"Should the analysis show other groups to be in favour of negotiating on regulations, we urge that discussions with the Minister be limited to those sections of the Act in which these groups are predominantly engaged."

WINCHESTER DIVISION

A meeting of the Winchester Division was held on Nov. 24, with Dr. C. J. Penny, O.B.E., in the chair. Of the 104 members in the Division 80 attended the meeting and 16 sent apologies (of whom 9 expressed their intention of voting against negotiations)—a record attendance.

Dr. Stevenson, assistant secretary of the B.M.A., opened the meeting by giving a clear account of the events leading up to the present National Health Service Act, the principles of the Act as pertaining to each section of the profession, and the implications to be deduced therefrom. He concluded by explaining the significance of a "Yes" or "No" vote. A fighting speech by Dr. Sybil Tremellen, of Winchester, who described the Act as an "infamous piece of tyrannical bureaucracy," was loudly applauded by the meeting.

Members had been previously asked not to record their answers until the implications of the plebiscite had been discussed at this meeting. Although no resolutions were put or votes taken (it being left to each member's own conscience as to the direction in which he should vote), the tone of the meeting was such that it was felt the majority of members were against negotiations.

The principal speaker in favour of negotiations was Lieut.-Col. C. Newton-Davis, who combined argument against the B.M.A.'s lack of negotiation with the Minister to date with a personal belief in the fallaciousness of Dr. Stevenson's address. There was no other convinced speaker on the "Aye" side.

WEEKLY POSTGRADUATE DIARY

BLACKPOOL: VICTORIA HOSPITAL.—*Thurs.*, 8 p.m. Dr. Hilliard: The Diagnosis and Treatment of Mitral Stenosis.

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Edinburgh Royal Infirmary, *Tues.*, 5 p.m. Prof. G. Marrian: The Biochemist's Approach to Problems of Pharmacological Activity.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, Leicester Square, W.C.—*Tues.*, 5 p.m. Dr. R. M. B. MacKenna: Principles and Practice of Treatment. *Thurs.*, 5 p.m. Dr. F. R. Bettley: Seborrhoeic Dermatitis.

APPOINTMENTS

BIRMINGHAM CHILDREN'S HOSPITAL.—Honorary Assistant Orthopaedic Surgeon, A. Innes, F.R.C.S. Honorary Assistant Ophthalmic Surgeon, A. A. Douglas, M.D. St. And., F.R.C.S. Ed.

HARDING, H. E., F.R.C.S., Honorary Orthopaedic Surgeon, National Hospital, Queen Square, W.C.1.

LONDON COUNTY COUNCIL.—The following appointments have been made in the mental health services of the Council at the hospitals indicated in parentheses. Deputy Medical Superintendent, J. Mack, Crawford, M.D., D.P.M. (Darenth Park). First Assistant Medical Officers, M. A. Walsh, L.R.C.P. and S.I., D.P.M. (Tooting Bec), and R. MacDonald, M.B., Ch.B., D.P.M. (St. Lawrence's).

ROCHESTER: ST. BARTHOLOMEW'S HOSPITAL.—Honorary Surgeon and Honorary Radiotherapeutic Surgeon, Gerald Townsley, M.D., F.R.C.S. Honorary Orthopaedic Surgeon, R. N. Martin, F.R.C.S. Ed

DIARY OF SOCIETIES AND LECTURES.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—*Tues.* and *Thurs.*, 5 p.m., Fitzpatrick Lectures by Sir Arthur MacNalty: The History of State Medicine in England, 1. From the Accession of Queen Victoria to the General Board of Health. 2. The Medical Department of the Privy Council.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS, 58, Queen Anne Street, W.—*Fri.*, 5 p.m. Mr. Victor Bonney: Myomectomy.

ROYAL SOCIETY OF MEDICINE

Section of Psychiatry.—*Tues.*, 5.30 p.m. Discussion: Leucotomy as an instrument of research. Openers: Dr. A. Meyer and Dr. T. McLardy: Neuropathological studies. Dr. S. Last and Dr. G. Greville: Electroencephalographic studies.

Section of Physical Medicine.—*Wed.*, 4.30 p.m. Discussion: The contribution of Physical Medicine to the care of the chronic sick. Openers: Drs. E. L. Sturdee, Marjory Warren, and A. R. Neligan.

Section of Neurology.—*Thurs.*, 8 p.m. Discussion: Treatment and prognosis of traumatic paraplegia. Opener: Dr. L. Guttmann, followed by Mr. E. W. Riches, and Drs. D. Whitteridge and P. Jonason.

Section of Ophthalmology.—*Fri.*, 3.15 p.m. Meeting at the Manchester Royal Eye Hospital. 10.20 a.m. Train leaves Euston. 3.15 p.m. Paper by Prof. Geoffrey Jefferson: The surgery of intracranial aneurysms. 4.30 p.m. Cases. 5.30 p.m. Discussion. 7.45 p.m. Dinner.

Clinical Section.—*Fri.*, 5 p.m. (Cases at 4 p.m.)

Section of Radiology.—*Fri.*, 8 p.m. Joint Meeting with the British Institute of Radiology and the Faculty of Radiologists in the Reid Knox Hall, 32, Welbeck Street, W. Discussion: Carcinoma of the stomach. Openers: Dr. J. L. Grout: X-ray diagnosis. Mr. H. Rodgers: Gastroscopy.

Section of Radiology.—*Sat.* (Dec. 14), 10 a.m. Joint Meeting at 32, Welbeck Street, W.1, continued. Discussion: Carcinoma of the stomach. Openers: Prof. M. J. Stewart: Pathology. Mr. Hermon Taylor: Surgery. Dr. Fairchild and Mr. Alan Shorter: Radiotherapy. Dr. D. Jennings: Statistics.

CHELSEA CLINICAL SOCIETY.—At South Kensington Hotel, 41, Queen's Gate Terrace, S.W., *Tues.*, 6.30 p.m. for 7 p.m. Discussion: Plastics in Surgery and Medicine. To be opened by Dr. S. Leader and Mr. R. Cutler.

DEWSBURY: STAINCLIFFE COUNTY HOSPITAL.—*Thurs.*, 8 p.m. Clinical meeting.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—*Fri.*, 7.30 p.m. Clinical meeting.

LONDON JEWISH HOSPITAL MEDICAL SOCIETY.—At Woburn House, Upper Woburn Place, W.C., *Thurs.*, 8.30 p.m. Presidential address by Mr. S. I. Levy: Some Principles of Urinary Surgery.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—*Mon.*, 8.30 p.m. Discussion: Modern Anaesthesia, to be introduced by Drs. F. T. Evans and Cecil Gray.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—At 26, Portland Place, W., *Thurs.*, 8 p.m. Prof. B. S. Platt: Colonial Nutrition and Its Problems. A discussion will follow.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

HENDISSON.—On Nov. 11, 1946, at Lady Willington Hospital, Lahore, to Margaret Mary, wife of Lieut.-Colonel R. J. Hendisson, I.M.S., a daughter.

MACKENZIE.—On Nov. 27, 1946, at the North Staffordshire Royal Infirmary, to Sheila (née Joyce), wife of K. G. F. Mackenzie, F.R.C.S., a son.

MILNER.—On Nov. 30, 1946, at the Old Surgery, Middlewich Road, Sandbach, to Edna (née Key), wife of Dr. A. P. Milner, a daughter.

RANKIN.—On Nov. 25, 1946, at Parkgrove Nursing Home, to Jean Eleanor (née Crunkshank), wife of Dr. R. Rankin, 35, Kersland Street, Glasgow, a daughter. Both well.

WILLIAMS.—On Nov. 20, 1946, at Rubislaw Nursing Home, Aberdeen, to Ann, wife of P. B. Williams, M.B., Ch.B., a daughter—Linda Michele Godolphin.

WOOLSTENCROFT.—On Nov. 4, 1946, to Diana, wife of Dr. Robert Woolstencroft, 116, Rossall Road, Cleveleys, Lancs, a brother for Robert Peter—Mark Neville.

DEATHS

BOSWELL.—On Nov. 17, 1946, at Hiltonhill, St. Boswells, Roxburghshire, Henry St. George Boswell, M.B., C.M. Edin., in his 90th year.

HERBERTSON.—On Nov. 23, 1946, suddenly, at Monkstone, Ferring-by-Sea, Icha Richmond Herbertson, M.B., Ch.B., devoted and dearly loved husband of Florence Adeline.

DIET AND CANINE HYSTERIA

EXPERIMENTAL PRODUCTION BY TREATED FLOUR*

BY

Sir EDWARD MELLANBY, K.C.B., M.D., F.R.S.

(From the Nutrition Building, National Institute for Medical Research, Mill Hill)

During the past twenty years or more dog-owners in this country and in the U.S.A. have been troubled by sporadic outbreaks of a nervous disorder which has been called canine hysteria, running fits, or fright disease. The condition seems to have been noted first in the southern States of the U.S.A. about 1916 and in England about 1924, and to have increased in intensity and distribution since then. Much has been written on the subject, and the disorder has at one time or another been ascribed to many causes. These include internal and external parasites; deficiency of certain food factors, especially vitamins B₁ and A; deficiency of an amino-acid such as lysine; excess of proteins; allergy to food constituents and other substances such as pollen; toxicity of flour from the Far East; yeast; meat and the method of cooking it; botulism; infection of a virus type or a complication of distemper; and, finally, heredity. In recent years, however, the majority of writers seem to have agreed that (1) food is the causal agent, though there is no agreement as to whether the trouble is due to a deficiency in the food or to a toxic agent; (2) dog-biscuits and proprietary foods are often implicated; (3) a wheat product is the most likely causal agent in the dog food, including the biscuits; and (4) excitement and physical strain influence the onset and frequency of the attacks.

Canine hysteria up to 1936 has been reviewed and discussed by Hewetson (1936); here, therefore, reference will be confined to some of the experimental investigations on the subject since that date. Melnick and Cowgill (1937) produced convulsive reactions in six adult dogs on diets in which gliadin was the sole protein and furnished 16% or more of the calorie intake. They also suggested that the toxicity of these high-gliadin diets might be due to protein sensitization. Arnold and Elvehjem (1939) found that a dog food made of wheat flour and meat scrap processed by dry heat caused fits in young dogs, which could be alleviated or prevented by adding to the ration a sufficient amount of unheated protein or protein-containing foodstuff. They thought that a lysine deficiency was involved. Later, however, the subject was again investigated by Wagner and Elvehjem (1944) in consequence of an unpublished observation by Parry that commercial wheat gluten produced symptoms of hysteria in dogs with great rapidity and intensity. They confirmed Parry's observation and suggested that the disease was caused by some toxic factor in the wheat products and not, as the 1939 work had suggested, by a deficiency of lysine. Further, they stated that the attacks were not prevented by vitamin A, vitamin B₁, hydrochloric acid, casein, or casein hydrolysate.

Canine Hysteria as Observed in this Laboratory

Although there is general agreement among writers as to the signs of the disease and the behaviour of the affected animals, it is possible that canine hysteria has been occasionally mistaken for and even superimposed on such conditions as vitamin A or vitamin B complex deficiency. It may be said at once that in the work to be described no such complication could occur, since the animals always received ample amounts of

yeast and vitamin A, except in a few experiments devised to test the effect of vitamin A deficiency on canine hysteria.

The actual observed state of the affected animals in the course of the work will now be given. Apart from the periods of the so-called "attacks," dogs subject to hysteria can usually be recognized by their general demeanour. As compared with normal dogs of the same litter, they tend (1) to be less interested in their surroundings; (2) to run or walk more slowly; (3) to lift their forelegs high when walking and to bounce along when running; (4) to have dry mouths; (5) to stand in a shady corner if the sun is shining and to resist persuasion to run about; and (6) to be less friendly and more frightened. Although the most severe attacks may develop suddenly, the above abnormalities are usually seen for some days before the onset of hysterical outbursts; the actual attacks seem to represent temporary exacerbations superimposed on a chronic abnormal condition.

Once having had fits, a dog will usually continue to suffer intermittent attacks until the diet is changed. The attacks may recur at intervals of several days or a number of fits of varying intensity may develop in one day; they tend to be induced by any sudden stimulus, nervous strain, or change of environment; even bringing susceptible dogs from an outside run to an indoor kennel often precipitates the attacks, as does moving the animals from their usual room to a warmer one. Lactating bitches appear to be particularly prone to hysterical fits.

If the harmful diet is continued for some months the fits may be reduced in number or even stop, but the animal's general behaviour remains abnormal, as described above. A time may come, however, when a dog which seems to be acquiring immunity suddenly suffers the most severe epileptiform fits and dies.

Attacks vary from what is called slight hysteria to true epileptiform fits. In *slight hysteria* the animal has a frightened look, and usually stands with either fore or hind legs rather apart and ears back. Jerking of the head backwards may be seen. At this stage the animal will sometimes shake itself, take a drink of water, and then recover. Often the attacks begin as above, after which the dog rushes across the cage or run, but after dashing into the wall sits down, quiet and dejected-looking, and then slowly recovers. This is recorded as *hysteria*. In more severe cases the animal sits in a sphinx-like posture; its head soon starts jerking, and the movement spreads throughout the body. Next it starts running round and round its cage, sometimes barking furiously, and either dashes into the walls, apparently without seeing them, or attempts to jump up them, overturning food dishes and water-pots, and getting both itself and its cage into a filthy condition. It may begin to recover at this stage, stop running, and stagger around like a drunken person. It will sit down, looking very miserable, but at the end of about 30 minutes may be more or less normal. This is recorded as a *hysterical fit*.

If the dog does not recover at this stage it goes on running, froths at the mouth, usually howls, and collapses. Even then it still moves its legs with a running movement. Finally this movement ceases and the animal remains still, with rather

* Preliminary report

deep breathing. After a varied time—5 to 30 minutes—which appears to bear a relation to the severity of the fit, it recovers consciousness, gets up, and staggers around with marked ataxia; then follow the recovery stages outlined for a hysterical fit. This is recorded as a true *epileptiform fit*. If the animal does not recover consciousness within about thirty minutes it usually dies, although it may remain in an unconscious state for anything up to 36 hours.

Basis of Present Investigation

By 1931 the idea had developed in this laboratory that outbreaks of hysteria were due to the bread portion of the diet, and, since that time, when any such outbreak has occurred the source of the bread supply has often been changed and the fits have usually ceased. Another method adopted empirically, and because we had never seen a dog develop this hysterical condition when oatmeal formed the major part of the diet, was to replace a half or more of the bread by oatmeal, and this was also effective in stopping the outbreak. Samples of the flour from which the suspected breads had been made were obtained for inspection, and thanks are due to a number of bakeries for help in this connexion.

During the period of the war it became necessary to obtain supplies of flour of known extraction and composition for experiments on nutrition, and the Cereal Division of the Ministry of Food arranged that these supplies should be prepared at one mill. The miller responsible for the production of the flour often kindly brought it in person to the laboratory, and it was natural to tell him that we suspected some flours of being responsible for outbreaks of canine hysteria and thought a bleaching or improving process might be doing the harm. He asked to be shown samples of the flours, and immediately on seeing them said that all had been heavily bleached and probably improved.

The following are the chemical agents in use for bleaching and improving flour (Lockwood, 1945; Smith, 1944):

Bleachers.—Nitrogen peroxide (gas); benzoyl peroxide (powder).
Improvers.—Ammonium persulphate (powder); potassium persulphate (powder); potassium bromate (powder); acid calcium phosphate (powder).

Combined Bleachers and Improvers.—Chlorine (gas); chlorine and nitrosyl chloride (beta gas); nitrogen trichloride (agene) (gas); chlorine dioxide (addage) (gas).

Thus there seemed a large choice from which to pick out the hypothetical offending agent. However, in discussing the matter further with the miller, the possible implication of wheat protein as the aetiological factor in canine hysteria was mentioned, reference being made to the results obtained by Melnick and Cowgill on gliadin and by Wagner and Elvehjem on wheat gluten respectively. Thereupon he said it was well known that the agene process, in which NCl_3 gas was used, affected the gluten of flour, and that this method of improving flour was used very extensively. On being challenged on this point, he said he would not be surprised if as much as 90% of flour milled in this country and used for bread-making was "agenized." He was therefore asked to supply this laboratory with agenized flour and an equal amount of untreated flour from the same grist so that the hypothesis could be experimentally tested. These are the flours described in this paper as treated (agenized) and untreated (no agene).

Agene is said to consist of approximately 1% nitrogen trichloride in air saturated with water-vapour. The gas is generated by bringing together chlorine, water, and ammonium chloride, and is removed from the solution by aeration; the air and gas are then brought into intimate contact with the flour in an agitator. The amount of agene used in any operation can be closely controlled and depends largely on the extraction rate of the flour or on the particular portion of the wheat berry milled.

Experimental Results

The flours were tested by feeding young dogs of the same litter on treated and untreated samples. The diet used was one known to be adequate and compatible with normal growth and health provided untreated flour or oatmeal was used as the cereal. It consisted of: separated milk powder, 20 g.; cereal, 50–340 g.; lean meat, 15 g.; peanut oil, 10 ml.; bakers' yeast,

5% of the cereal; ascorbic acid, 5 mg.; NaCl , 1–2 g.; vitamin A, 2,000 or 3,000 i.u.; and vitamin D₃, 200 i.u. The cereal of the diet was cooked in a steamer for 90 minutes at a pressure of 0.5 lb.

It soon became evident that the hysterical outbreaks could often be produced by the above diet if it contained the treated flour but not if it contained the untreated flour. In young puppies the attacks came on insidiously and usually took some weeks to develop. In older growing animals, whose appetites were larger, it was often possible to produce the condition more quickly—sometimes after a fortnight or less of feeding on a diet which included agenized flour. The degree of susceptibility varied from litter to litter and even from animal to animal in the same litter. Changing the flour in the diet of a badly affected animal to the untreated variety resulted in a sudden stoppage of the fits, but the animal might remain nervous and shy for a period.

Tables I–III show the effect of the treated (agenized) as against the untreated flour in regard to the number of hysterical attacks and fits produced in the animals. Attacks of slight hysteria have not been tabulated, but these were numerous in the animals receiving treated flour and were never seen in those having untreated flour. All the attacks recorded were observed, except those in the column headed "probable fits," which were deduced from the condition of the animal and its cage after periods when observation was not continuous. Many of these so-called "probable" fits were without doubt severe hysterical fits, for both animals and cages were filthy, water-pots and food dishes were overturned, and sawdust scattered, as was the case after observed fits. The cages of the animals receiving treated flour were often found in this condition in the early morning, suggesting that the night may be a common time for the attacks; but, since the severity of an attack could not be judged solely from the state of the cage after a lapse of possibly several hours, these hypothetical fits have not been included in the tables.

TABLE I

Dog No.	Type of Flour	Time to First Attack	Hysteria	Hysterical Fits	Epileptiform Fits	Probable Fits	Total
1st Period (24 weeks)							
3175	Untreated	—	0	0	0	0	0
3176*	Treated	4 weeks	0	10	5	5	20
3177	"	"	9	10	6	5	30
2nd Period (12 weeks)—Flour reversed							
3175	Treated	1 week	15	6	1	2	24
3177	Untreated	—	0	0	0	0	0

* Died after 6 weeks on diet, after having continuous epileptiform fits for two days.

It is seen from Table I that during the first period of 24 weeks dog 3175, receiving untreated flour, had no hysteria or fits, while 3177, which received the treated flour, had 30 attacks of various kinds. During the second period, lasting 12 weeks, when the types of flour were reversed, dog 3175 suffered from 24 attacks and 3177 had none.

TABLE II

Dog No.	Type of Flour	Time to First Attack	Hysteria	Hysterical Fits	Epileptiform Fits	Probable Fits	Total
3187*	Treated	4 weeks	5	7	3	1	16
3188	"	"	4	9	0	4	17
3189	Untreated	"	0	0	0	0	0
3190†	Treated	4 weeks	4	13	6	4	27
3191	"	"	5	11	2	3	21
	Untreated	"	0	0	0	0	0
3192	(1st 15 weeks) Treated (8 weeks)	2 weeks	2	2	0	1	5

* Died after 23 weeks on diet after having a severe epileptiform fit.

† Died after 15 weeks on diet after having continuous epileptiform fits for 36 hours.

Table II also shows how definite is the effect of the agenized flour. The one dog of the litter having the untreated cereal throughout, No. 3189, had no hysterical bouts or fits during the experimental period of 22 weeks, whereas the four having treated flour all the time had attacks varying in severity and ranging in number from 16 to 27 during this period. The last

the series, No. 3192, whose diet was changed in the course of the experiment, had no fits during the 15 weeks it received untreated flour, but two weeks after the substitution of treated (agenized) flour the attacks started, and it had five of them.

Vitamin A Deficiency and Canine Hysteria

Canine hysteria can be superimposed on vitamin A deficiency when animals have a diet deficient in vitamin A and containing agenzized flour. Examples are seen in Table III, which shows the results of an experiment made on four dogs of the same litter, two of which had the basal diet described above, containing 2,000 i.u. of vitamin A daily, and the other two had the same diet with the omission of the vitamin. No hysteria or fits developed in any of the dogs during the 15 weeks when untreated flour was given, whether vitamin A was included in the diet or not. In the second period treated (agenized) flour was substituted for the untreated type in each case, and all our animals suffered to some extent from hysteria or fits, though the vitamin A content of the diet remained the same during the first period. After 10 days on this diet untreated flour was again given to two of the animals—Nos. 3203 and 3205—the first being vitamin-A-deficient and the other normal. The flour has now been changed for one month, but, except during the first day, neither dog has had any form of fit, and, though not yet fully recovered, they have had no outburst which could be rated even as slight hysteria.

TABLE III

Dog No.	Vitamin A, in Diet	Type of Flour	General Condition of Animal	Hysteria and Fits
1st period (15 weeks)				
201	—A	Untreated	Definite A deficiency	None
202	+A	"	Normal	"
203	—A	"	Definite A deficiency	"
205	+A	"	Normal	"
2nd period (10 days)				
201	—A	Treated	Definite A deficiency	Slight hysteria
202	+A	"	Normal	4 hysterical fits
203	—A	"	Definite A deficiency	8 severe epileptiform fits
205	+A	"	Normal	4 " "

Discussion

The results of this investigation show that the practice of bleaching and improving flour by NCl_3 , known as the agene process, is responsible for a flour which produces canine hysteria under the conditions described above. The evidence is of a direct kind, the abnormality being produced by diets containing the treated flour, samples of the same flour untreated being harmless. Substitution of the treated flour by the untreated type tends to reverse the animal's condition and allows complete recovery from the hysteria and fits, even though the animal itself may not be normal. Recovery from the slighter but more chronic condition appears to bear a relationship to the length of time the animals have received the treated flour. If they have had it for a long period—e.g., six months—recovery may not be complete even after three to four months on the untreated flour, although the more severe abnormalities, such as hysterical and epileptiform fits, will cease within 24 to 48 hours of the change of diet.

In this connexion the Report of the Departmental Committee on the Treatment of Flour with Chemical Substances (1927) states: "An obvious method of investigating the presence of harmful compounds or suspected impairment of nutritive properties is by feeding experiments with animals. When such experiments give positive results they are conclusive, but negative results cannot be regarded as innocuous." The results described in this paper are of the positive kind referred to in this statement. It is, however, of interest to note that during the course of the present work feeding experiments on rats with agenzized flour were negative, just as similar experiments referred to in the report of the Departmental Committee on feeding rats with flour treated commercially with chlorine and nitrogen trichloride were "inconclusive."

It is agreed by experts in milling practice that the agene process affects the gluten of flour particularly. In the above-mentioned report it is stated that "chlorine can act energetically upon gluten, and that the nature of the reaction includes the entrance of chlorine into such important parts of the gluten

complex as the tyrosin and tryptophane groupings"; and, later, that "our observations upon chlorine apply also to nitrogen trichloride" and "evidence has been given that its action [i.e., that of NCl_3] on the protein of flour is probably similar to what we have already described in the case of chlorine." No experiments have been made in the present work with flour bleached and improved by chlorine.

These statements from the report, written nearly 20 years ago, taken in conjunction with the results obtained in the present work showing the toxic effect of agenzized flour, must be considered in relation to the work of Melnick and Cowgill (1937), of Parry, and of Wagner and Elvehjem (1944), referred to earlier, and it would be a matter of interest to know whether the gliadin and gluten used by the U.S.A. workers were prepared from agenzized flour. It is believed that this process of improving flour is, or has been, as popular in the U.S.A. as in this country, so it is not unlikely that the proteins used by the U.S.A. workers were prepared from agenzized or similarly treated flours. Obviously the next test to be made in regard to canine hysteria was to compare the effects of wheat gluten made from untreated and agenzized flour respectively, and this is now being done.

When the idea of testing the effect of agenzized as against untreated flour was first mooted the point was raised that, though proprietary dog-biscuits were said to be associated with canine hysteria, it seemed unlikely that the flour used in such biscuits would be agenzized. The miller, however, said that, although flour intended solely for dog-biscuits would not usually be subjected to an improving process, a long-extraction flour which had been so treated was, in fact, often used in their manufacture. Indeed, he regarded this fact as supporting the idea that agenzizing might well hold the solution to the problem of the observed hysterical attacks and account for the variations in reports implicating dog-biscuits.

The agenzized flours used in this investigation were not specially prepared overbleached specimens, but, according to our miller friend, were all subjected to a normal commercial bleach. At different times the extraction rate of the flours has varied between 80 and 90%. Some batches have had no added calcium and others have had the normal statutory additions, prescribed for 85 and 90% extraction flours, but all, irrespective of calcium content or extraction rate, have given the same results so far as canine hysteria is concerned. It is possible to increase the bleach in order to camouflage a clumsy separation in the mill. It is likely that such a flour would be even more powerful in producing the hysterical condition here described.

The abnormal behaviour of the animals affected by the agenzized flour suggests that the central nervous system is primarily affected by some toxic agent, but other organs may also be involved. A few dogs have died in these attacks, but ordinary post-mortem examination has not yet revealed any lesion which can be regarded as the essential one. It is clear that investigations must now be made to see whether human beings are affected by bread made from flour improved by NCl_3 .

Summary

Canine hysteria, sometimes called running fits or fright disease, a nervous condition which has troubled dog-owners both in this country and in the U.S.A. for the past 20 years or so, has been produced in growing dogs by including in their diet flour that has been improved and bleached by NCl_3 , the agene process. The same flour when untreated did not produce the nervous malady. Affected dogs returned towards normal and the typical hysteria and fits stopped when the agenzized flour was removed from the diet and replaced by unimproved flour of the same grist.

Warm thanks are due to the miller mentioned above, who wishes to remain anonymous, for the help he has given in this work. Not only did he supply with promptness and great care the specimens of flour needed for the research, but he also placed his specialist knowledge as a scientific miller at our disposal and so made the investigation possible. I wish also to thank members of the staff of the laboratory, especially Mr. R. J. C. Stewart, for their help and zeal in this work.

2-THIOURACIL IN THE TREATMENT OF CONGESTIVE HEART FAILURE

BY

E. P. SHARPEY-SCHAFER, M.R.C.P.

Physician and Senior Lecturer, Department of Medicine,
the British Postgraduate Medical School

It has long been thought that removal of the influence of the thyroid gland might prolong life in cases of congestive heart failure. The theoretical purpose of such treatment is usually stated to be reduction of the total oxygen requirements of the body and decrease in the work of the heart (Blumgart, Levine, and Berlin, 1933; Fishberg, 1940). Total thyroidectomy has not proved entirely satisfactory, since the immediate mortality in severe cases was high (Cutler and Hoerr, 1941). The development of the goitrogenic substances for clinical use (Astwood, 1943) has indicated another possible method of diminishing thyroid activity, and this paper reports the effects of 2-thiouracil on cases of congestive heart failure which had failed to respond to ordinary methods of treatment and in which the immediate prognosis was poor.

Methods

The methods were similar to those published previously (McMichael and Sharpey-Schafer, 1944a; Howarth, McMichael, and Sharpey-Schafer, 1946), cardiac output and right auricular pressure being measured by cardiac catheterization. The observations were made with the patient's trunk elevated 45°. Right auricular pressure is about -7 cm. (sternal angle=0) in normal subjects in this position. The work of the heart is calculated arbitrarily from the product of the cardiac output and the blood pressure.

Results

Cases of severe congestive failure treated with thiouracil may be divided into two groups: low-cardiac-output heart failure (hypertensive and valvular heart disease) and high-cardiac-output heart failure (heart failure with emphysema). Initial data before thiouracil are shown in Table I. Cases 1, 3, 4, and 5 showed the usual response of their group to a fall in venous filling pressure—i.e., an increase in cardiac output. The slight fall in output after venesection in Case 2 indicated a less severe case. In the most severe cases, 6 and 7, little change in cardiac output was produced by a decrease in venous filling pressure. Starling's venous pressure—cardiac output curve has been suggested as a convenient concept for indicating the status of an individual heart (McMichael and Sharpey-Schafer, 1944b). In the emphysema group the usual status lies near the highest point of the curve, so that a fall of venous pressure results in a decrease in cardiac output (Cases 8, 9, 10, and 11). Only the most severe cases show an increasing output (Case 12) similar to the low output group. Several cases had a long period of treatment by ordinary methods—rest in bed, digitalis, and venesection in the low-output-heart-failure group and prolonged sojourn in an oxygen tent in the emphysema group. In some patients this treatment had caused little or no clinical improvement, the venous pressure remaining high.

Clinical Effects of Thiouracil.—The dosage of thiouracil and results of treatment are shown in Table II. No clinical benefit from thiouracil can be expected under a week or ten days. Fig. 1 (Case 1) shows an example of the fall of venous pressure

FIG. 1.—Case 1. Venous pressure fell and there was a diuresis after 10 days on thiouracil. V=Venesection. M=Mercurial diuretic

and disappearance of oedema in a successful case. The long period of observation under treatment by ordinary methods in several cases makes spontaneous improvement unlikely. After several months on thiouracil signs of thyroid deficiency appear. The mental reactions and movements of the patient become slower. The skin becomes thickened, the hair dry, and the voice deeper and hoarser. In some cases the thyroid gland appears to increase in size; in others no enlargement is detectable. Agranulocytosis did not develop in any of these cases of congestive heart failure.

Effect on Oxygen Consumption.—Basal and resting oxygen consumption are reduced by thiouracil (Fig. 2). The basal

FIG. 2.—Case 2. Effect of thiouracil on basal oxygen consumption. Metabolic rate is usually increased in congestive heart failure. Prolonged treatment with thiouracil did not decrease the basal metabolic rate below -25% in any of these cases.

Effect on Cardiovascular Dynamics.—Results in a case from each group are shown in Table III. In Case 1 cardiac output was the same after thiouracil as during the control period, for although resting oxygen consumption was less, the arterio-venous oxygen difference had decreased in parallel. Since the blood pressure was the same, the work of the heart did not

change. In Case 9 the high initial output decreased to a normal level. This was due not only to a decrease in the oxygen consumption but to an increase in the arterio-venous oxygen difference.

Effect on Thyroid Gland.—Detailed histological studies will be reported elsewhere on two surgical biopsies and ten post-mortem specimens (Doniach and Sharpey-Schafer, to be published). Clear-cut evidence of stimulation was present in cases receiving more than 70 g. The average weight of hyperplastic glands was not significantly greater than that of control untreated cases. Colloid re-formed and follicular epithelium was reduced in weight within a few months of cessation of thiouracil treatment.

Discussion

"Clinical improvement" in patients with severe chronic congestive failure may be defined as a change which shows itself by a fall of venous pressure towards normal levels and an increase in exercise tolerance, which allows the patient to get about or to leave hospital. This definition covers both the high-output and the low-output groups. The data presented in this paper suggest that some cases which have reached a chronic state on ordinary methods of treatment will show "clinical improvement" when the activity of the thyroid gland is depressed by thiouracil. No benefit can be expected in cases which are becoming rapidly worse, since there is probably little effect on thyroid activity under ten days.

The exact mechanism by which induction of a hypothyroid state results in improvement is still uncertain. It involves the nature of the changes producing "congestive heart failure"—a subject on which our knowledge is as yet scanty. When the venous filling pressure is lowered by venesection or digitalis in cases of low-output heart failure, the cardiac output increases, and "clinical improvement" is associated with increased work of the heart (McMichael and Sharpey-Schafer, 1944b; Howarth, McMichael, and Sharpey-Schafer, 1946). In these cases, however, the oxygen consumption is unchanged as an immediate result of treatment.

Case 1 shows that the work of the heart may not change after thiouracil, and it is probable that some cases of low-output heart failure may show increased work in the hypothyroid state. In cases treated with thiouracil, although cardiac output may be unaltered it is maintained at a lower filling pressure and in relation to the oxygen consumption of the individual it is relatively increased.

Detailed studies on cases of heart failure with emphysema will be reported elsewhere, but in view of the poor prognosis in this group it is encouraging that even a few cases can be improved sufficiently to leave hospital.

Summary

Cases of severe congestive heart failure showing no response to usual therapy (bed-rest, digitalis, and mercurial diuretics) were given 2-thiouracil 1 to 2 g. a day over long periods. Life may be prolonged both in the low-cardiac-output cases (valvular and hypertensive heart disease) and in the high-cardiac-output cases (heart failure with emphysema).

In the low-output group the arterio-venous oxygen difference may decrease as well as the resting oxygen consumption. The work of the heart may be unchanged, but output is maintained at a lower venous pressure, and in relation to oxygen consumption cardiac output is relatively increased.

Cases of high-cardiac-output heart failure with emphysema may improve sufficiently to leave hospital in spite of permanent reduction of arterial oxygen saturation.

There is histological evidence that the thyroid returns to normal after stopping thiouracil.

These observations were made in collaboration with Dr. John McMichael and Dr. Sheila Howarth. The Medical Research Council defrayed some of the expense.

Assistant nurses who have been enrolled by virtue of two years' whole-time nursing experience acquired since Sept. 3, 1939, may be granted a remission of six months in the normal three-year period of training for State registration. This concession is already available to men and women who have had suitable nursing experience in the Forces or as members of the Civil Nursing Reserve, the British Red Cross Society, or the St. John Ambulance Brigade, and the Minister of Health has now informed hospital authorities of its extension to assistant nurses. Applications should be made to the hospital at which the applicant wishes to train. A concession in the period of training for the Tuberculosis Association's certificate is also announced.

DIAGNOSIS OF CHRONIC DYSENTERY IN SERVICE PERSONNEL

ANALYSIS OF 1,000 SIGMOIDOSCOPIES

BY

Air Commodore T. C. MORTON, M.D., F.R.C.P.

R.A.F. Institute of Pathology and Tropical Medicine

The conclusion of hostilities has led to the demobilization of large numbers of Service personnel, many of whom have served in the Tropics, and an aftermath of recurrent dysenteries and chronic diarrhoeas will be inevitable in a small minority on their return to civil life. It is felt that an analysis of 1,000 diagnostic sigmoidoscopies carried out in the last two years will be of interest. The cases under review were either invalided home with a diagnosis of chronic amoebic or bacillary dysentery or returned to the United Kingdom at the expiration of their tour overseas, and were referred by their station medical officers in England for a sigmoidoscopy in view of their symptoms. In addition, a small group of men who had been invalided from overseas for surgical or other reasons were found to be *Entamoeba histolytica* cyst carriers on routine stool examinations and were sigmoidoscoped. A small series of sprue cases are included, as early in the course of these investigations we were surprised at the number of undetected cases of dysentery among them.

Method

Sigmoidoscopies were carried out in the knee-elbow position without an anaesthetic. The new type plastic sigmoidoscopes were used; these take a 6-volt car bulb light and give an excellent illumination, and a magnifying eyepiece of 4 diameters was invariably used. The question of preparation is a most important one, as any preliminary bowel washout within six hours of sigmoidoscopy, even with normal saline or tap water, produces a hyperaemia that renders extremely difficult, if not impossible, the identification of the "raised crateriform pits" pathognomonic of chronic quiescent amoebiasis; this is the reason why this characteristic pitting is so often missed.

The following preparation was eventually adopted. On the previous day a light lunch and tea are followed by a bowel washout with ordinary tap water at 8 p.m.; no supper is given that night. No breakfast or early cup of tea is allowed on the morning of the examination. A natural call to stool must be obeyed, but the patient should make no attempts at voluntary straining; the bladder should be emptied immediately before examination. A scraping and swab from any suspicious area should be mounted and examined without delay for *E. histolytica*, and a warmed plate of Hynes's modification of Leifson's desoxycholate citrate medium inoculated and cultured. If there is no obvious lesion a culture should be made from a direct swabbing of the bowel wall, and any faeces adherent to the bowel wall examined for *E. histolytica*.

Out of 1,000 cases sigmoidoscoped at this institute only 513 gave positive findings; in the remaining 487 both sigmoidoscopy and laboratory investigations were negative (see Table I). The positive laboratory findings were as follows: Amoebiasis, 215 (mixed amoebic and bacillary dysentery—11); bacillary dysentery, 52 (Shiga 2, Schmitz 3, Sonne 4, Flexner 43); lambiasis, 40. In approximately 20% of the 215 amoebic cases the sigmoidoscopic appearances were normal. In bacillary dysentery, out of 52 positive laboratory findings the appearances were normal in 9 cases. (Two cases were not sigmoidoscoped before treatment.)

Amoebiasis

The amoebic ulcers found conformed to the textbook descriptions, but 5 cases of amoeboma were encountered in cases of amoebiasis which had remained unrecognized for long periods. Dyak hair sloughs were present in only 4 cases, and all these were extremely refractory to treatment.

Raised crateriform pits, in my opinion, are pathognomonic of quiescent amoebiasis. They were present in 169 patients, in 78 of whom *E. histolytica* were found in the stools. The crateriform pits are circular in shape, from 1 to 2 mm. in

diameter, and are raised about a millimetre above the surrounding mucosa. In order to recognize them it is essential that no bowel washout be administered for at least six hours before the examination, as the resultant hyperaemia caused by even so bland a fluid as normal saline will completely obscure the A good description of these pits has recently been published by Cropper (1945). My only criticism of his excellent article is that I consider a half-strength soap-and-water enema given six hours before a sigmoidoscopy absolutely contraindicated by the resultant hyperaemia. It is usually impossible to find *E. histolytica* in scrapings taken directly from the pits owing to the amoebae lying dormant deep in the submucosa; but their presence calls for repeated and persistent search of the stools for cysts. I do not hesitate to treat cases showing this characteristic pitting even if the stools are negative, as look upon the condition as positive evidence of quiescent amoebiasis; in the majority these pits completely disappear after specific anti-amoebic treatment, or are replaced by circular depressions in the mucosa. In a small number of cases where these pits have still been present after specific treatment at the stools were negative I have allowed the patients to leave hospital under surveillance, only to find that sooner or later they have had a clinical relapse with positive stool findings. These raised crateriform pits must not be confused with the pseudo-cystic "sago grain" follicles occasionally following bacillary dysentery (Manson-Bahr, 1943). The essential point of the amoebic pits are their regularity, concentric appearance and the presence of the circular lip of the volcano surrounding a slightly depressed crater. Raised lymphoid follicles may also be distinguished from these crateriform pits; they are evidence of a lymphoid hyperplasia, and again the distinguishing feature is the absence of the central pit. It is difficult at times to be certain whether the pits are still active at the conclusion of treatment; a gentle swabbing giving rise to petechial bleeding at the site of the pits is always suggestive, and a further test is to provoke an artificial diarrhoea by giving the patient salts thrice daily for three days and examining fresh stools passed in the laboratory annexe.

Depressed pits were present in 126 cases. *E. histolytica* was found in 20 of these, and the explanation is that active lesions were probably present higher up in the colon. Pitting is frequently seen in healed bacillary dysentery cases (Hamilton Fairley and Boyd, 1942); but here it is more irregular in shape and size, is tessellated, and lacks the circular uniformity of pitting in amoebiasis, which has been aptly described as "pitted skin pitting," and is, in my opinion, evidence of healed amoebiasis.

Symptomless Cyst Carriers.—It is the practice in R.A.F. hospitals for all patients who have been invalided home from overseas to have a complete blood count and three stool examinations; as a result of this 58 symptomless cyst carriers were detected. A sigmoidoscopy was carried out before starting treatment, and in 16 cases typical crateriform pits were seen. In one case, in addition to active pitting, a small superficial ulcer some 2 mm. in diameter was present on the anterior wall of the rectum, although the patient categorically denied any symptoms referable to the intestinal tract. It is assumed in the 42 cases in which the sigmoidoscopic appearances were normal, that lesions were present out of range of the sigmoidoscope.

Complications of Amoebiasis

Amoebic Abscess.—Ten cases occurred in this series, which 8 developed overseas. In 2 of the latter a spontaneous rupture of the abscess into the general peritoneal cavity was diagnosed only at operation, and in both the abscess was the left lobe of the liver.

Amoebic Hepatitis.—In a total of 60 cases only 4 developed in England. A moderate leucocytosis was found to be of great value in the differential diagnosis, and a routine screening of the diaphragm was carried out in every case of amoebiasis. The lowest total white cell count recorded before treatment was begun was 14,200 per c.mm., the highest 27,500; the average for the series was 15,800 with 75% polymorphonuclears. It is recommended that, as this finding is so constant, a total white and differential count should be carried out in every case of amoebiasis to exclude amoebic hepatitis. The

value of this constant leucocytosis was first stressed by Manson-Jahr (1943). Paradoxically the total white cell count may not be raised in a small proportion of cases of amoebic abscess of the liver.

Amoeboma or Amoebic Granuloma.—This may be defined as a hyperplastic localized tissue reaction of the colon, the hypertrophy chiefly affecting the submucosa, which is infiltrated with lymphocytes, histiocytes, and plasma cells, together with *E. histolytica* in localized clusters. The condition is relatively rare, but occurs in a chronic unrecognized amoebic infection and is liable to be mistaken for a neoplasm. The symptoms are usually atypical, and it is felt that, unless surgeons are warned of the possibility of its occurrence, many cases may be operated upon unnecessarily, with disastrous results. Five cases were detected—4 at home, and 1 overseas in an expatriate; in 4 out of the 5 the growth was within the range of the sigmoidoscope. It is in these cases that the protean manifestations of amoebiasis lead the clinician astray, the usual symptoms being a history of intermittent attacks of alternating diarrhoea and constipation associated with the occasional passage of blood, which is as a rule attributed to the concomitant haemorrhoids so often present. On physical examination the finding of a palpable abdominal swelling or a fungating cauliflower mass in the rectum naturally suggests malignancy. In one case, which had remained unrecognized for many months in various hospitals, it was only on taking scrapings from the

reports an incidence of 1% of rectal stricture in chronic amoebic dysentery; possibly a similar aetiology is responsible.

Amoebiasis Simulating Appendicitis.—Four cases of this occurred, where, following an appendicectomy in India, acute amoebic dysentery ensued within 48 hours of the operation, and it is probable that the symptoms were due to an amoebic involvement of the caecum. Perforation of an amoebic ulcer of the caecum occurred in one case which was operated on successfully in India.

Malignant Disease.—Six cases of adenocarcinoma of the rectum or sigmoid were seen. In only one patient had this diagnosis been made overseas, and ironically he developed amoebic hepatitis while convalescing from his colostomy in the United Kingdom. The ages of the patients were 31, 37, 38, 39, 43, 43 years, which is considerably higher than the mean age group of this series—namely, 26 years. In only two cases had *E. histolytica* been found, and all the cases had received repeated courses of treatment for amoebiasis or bacillary dysentery with no effect, in spite of negative laboratory findings. In three cases the growth was within reach of the examining finger, and the pronounced induration present suggested malignancy rather than amoeboma.

Lambliasis

Cysts or free forms were found in only 40 cases, in 18 of which infestation appeared to be giving rise to a chronic

TABLE I—Sigmoidoscopic Appearances in 513 Cases with Positive Findings

Miscellaneous Findings:

Adenocarcinoma	6
Multiple polyps	1
Ulcerative colitis (idiopathic)	7
(6 completely negative laboratory findings at home or overseas. Sigmoidoscopy typical.)	

ulcerated growth in the rectum that the diagnosis was made and *E. histolytica* was demonstrated for the first time: six previous examinations of the stools had been completely negative. Stenosis of the lumen of the bowel is often present, but after a course of emetine and penicillin the growth simply melts away and fibrosis and stricture rarely develop. If the response to specific treatment does not lead to the complete disappearance of the growth a dual pathology must be considered and laparotomy is necessary, as in a case recently reported by Naunton Morgan (1944).

Stricture of the Rectum.—This, as a remote complication of amoebic dysentery *per se*, probably rarely occurs. However, one case was seen in this series in which the diagnosis was fully substantiated, though the actual pathology is open to conjecture. The patient, a proved case of acute amoebic dysentery, while undergoing routine specific treatment developed an acute exacerbation followed by the passage of a large slough per anum, which on section was shown to be a separation *en masse* of the inner bowel wall; attempts to isolate bacillary dysentery organisms were unsuccessful. Stenosis followed this sloughing, and a colostomy was carried out in India. On his return to the United Kingdom an attempt was made to close the colostomy, but the wound broke down and active *E. histolytica* were found in the discharge and also in a biopsy from the site of the stricture; this in spite of the fact that all stool examinations had been negative for the last three months and he had received intensive anti-amoebic treatment in the interim between the first and second operations. The aetiology here is obscure, but it is possible that the sloughing of the bowel wall was due to a massive secondary bacterial invasion in a mucosa that was the site of extensive amoebic ulceration. Hargreaves (1946)

diarrhoea for which no other cause could be found, and the symptoms disappeared after mepacrine therapy. This surprisingly low incidence (4%) of lambliasis is probably due to the fact that the majority of these patients had received repeated therapeutic courses of mepacrine for malaria. In three instances *Lamblia intestinalis* was found in patients who had been taking suppressive mepacrine in the normal dosage over long periods. Whittingham (1923) in a similar series of 716 cases found 8% of cases of lambliasis, so one can presume that suppressive mepacrine has cut down the incidence.

Bacillary Dysentery

The large number of cases in which the causative organism of bacillary dysentery was cultured from sigmoidoscopic swabbings and from fresh stools in these chronic cases is surprising, especially in view of the disappointing results obtained in the past (Martin and Williams, 1918). These results must be due to the extreme selectivity of the modern media, as in 31 of the 52 cases the diagnosis had never been made overseas. The majority of the cases had been treated for amoebiasis with little benefit. Table II gives the various strains isolated together with the geographical distribution.

The sigmoidoscopic appearances in the bacillary dysentery cases under review were:

- (1) A generalized hyperaemia with excess of mucus.
- (2) A general hyperaemia with a tubular stenosed lumen, the mucosa having a granular appearance and bleeding readily on instrumentation, which is painful. The patient passes some six to eight stools a day. The prognosis is poor in this type of case.
- (3) Superficial oval or circular ulcers up to 1 cm. in diameter: the bowel wall distends readily, and there may be no inflammation

of the intervening mucosa. These lesions are particularly liable to be mistaken for those found in amoebic dysentery. One such case was encountered recently in which the appearance mimicked an amoebic ulcer so closely that it was only after two scrapings from the ulcer had been fruitlessly examined for *E. histolytica* that a third scraping was cultured and *B. flexneri* VI isolated. Hamilton Fairley and Boyd (1942) report similar cases.

TABLE II.—Geographical Distribution of Bacillary Dysentery

(4) A puzzling appearance which is, however, characteristic of chronic bacillary dysentery and was first reported by Manson-Bahr is a pseudo-cystic condition arising from the occlusion of the crypts of Lieberkühn. The appearance suggests "sago grain" elevations varying in size from 1 to 3 mm. scattered over the mucosa; sometimes the entire mucosa is studded in this way. These "cysts" on rupture are found to contain clear or blood-stained mucus, from which the causative organism can frequently be isolated by culturing direct swabbings obtained at sigmoidoscopy. One such case was invalidated from Italy with a diagnosis of multiple polyposis, but on rupture of these cysts *B. flexneri* III was isolated on culture.

Hamilton Fairley and Boyd (1942) in an admirable review of the sigmoidoscopic findings in bacillary dysentery state: "(1) In our opinion all bacillary dysentery carriers have lesions of this or a similar type somewhere in the colonic mucosa. (2) The bacilli are derived from the ulcers. (3) Once the ulcers have completely healed dysentery bacilli disappear from the stools."

Complications of Bacillary Dysentery

Complications were relatively infrequent, this undoubtedly being due to the introduction and extensive use of sulphaguanidine in all cases of severe diarrhoea overseas. Two cases showed a general narrowing of the rectum, associated with a granular, hyperaemic, easily traumatized mucosa. The prognosis in this type of case is poor, the patient being condemned to a life of semi-invalidism for many years, if not indefinitely. Two cases of arthritis of the ankle-joint developed during the course of an attack of acute bacillary dysentery overseas, complete recovery following in both cases with no residual arthritis.

Ulcerative Colitis (Idiopathic).—Seven cases were diagnosed, in six of which laboratory investigations were completely negative for bacillary dysentery and agglutinations carried out against bacillary dysentery were inconclusive. In one case both bacillary and amoebic dysentery were confirmed by laboratory findings overseas, but investigations here were fruitless. The association between bacillary dysentery and ulcerative colitis, so strongly stressed by Felsen (1945), has therefore not been found except in one case, and temperamentally this patient showed no evidence of the typical ulcerative colitis diathesis.

Hyperplastic Colitis.—Four cases were seen. The sigmoidoscopic appearances were identical, consisting of deep greyish depressions, the site of healed ulcers, surrounded by overhanging hypertrophied bridges of red mucosa giving one the impression of a rabbit warren. The mucosa bridged the depressions, and in one instance divided the lumen of the bowel into two; the remaining mucosa was unaffected and of a much paler colour than the affected part. The only symptoms were pain and bleeding following constipation, and in one case it was found necessary to divide a band of mucosa bridging the lumen of the bowel; this was carried out by Mr. Lloyd Davies, to whom I am indebted for the biopsy. The sections showed a rather hyperplastic mucosa with no evidence of inflammatory change. No pathogens were discovered in any of these cases on their return to England, but two of them were said to have had amoebiasis overseas. Three of them have been kept under observation for over a year, and, provided the bowels are

regulated, they suffer no ill effects and are in perfect health. Sir Philip Manson-Bahr kindly examined one case and considered it was a sequel to bacillary dysentery. Agglutinative were carried out for bacillary dysentery, and one case agglutinated *B. flexneri* I in 1/50; the other three were completely negative. It is probable that this condition is an excess healing response to extensive ulceration—a mucosal hypoplasia analogous to keloid.

Post-dysenteric Colitis.—In 16 cases a residual colitis persisted after treatment; in only one case was it necessary to invalidate the patient out of the Service. The other 15 have been kept under observation, and there has been a slow but gradual improvement in their condition; check-up sigmoidoscopies reveal a definite improvement. It is difficult, however, to convince a colon-conscious patient that improvement has occurred despite the objective evidence of gain of weight, when a flatulent properties of a post-war carbohydrate diet produce a cogent but fallacious evidence to the contrary.

Sprue Syndrome

Numerous cases have been invalidated from India with a diagnosis of sprue or para-sprue. In some cases the syndrome developed within four months of the man's arrival in India. The usual history is of an attack of non-specific enteritis shortly after disembarkation, followed by recurrent attacks of diarrhoea, bacillary or amoebic dysentery. The response to specific treatment is at first good, but the tendency to recurrent attacks of diarrhoea persists, and finally the patient notices that stools are copious and pale and complains of a flatulent dyspepsia and intolerance to fatty foods. There is rapid loss of weight, and in many cases a soreness of the tongue develops with or without an anaemia. A flattened low blood-sugar curve is commonly present and persists for some time after specific sprue treatment, and its return to a normal curve is a useful index of recovery.

Eighty cases invalidated from India with a diagnosis of sprue or para-sprue were sigmoidoscoped and investigated on the same lines as the dysentery cases. It was found that 46% of them were harbouring pathogenic intestinal protozoa or bacteria, and that after eradication of this concomitant infection the sprue symptoms responded more readily to the routine orthodox treatment for sprue. A detailed analysis of the findings is given in Table III. It was possible to compare the

TABLE III.—Analysis of Findings in 80 Cases with Sprue Syndrome

Laboratory Investigations Negative	Laboratory Investigations Positive			
	<i>E. hist.</i> Positive	<i>L. lamblia</i>	Mixed Bacillary and Amoebic	Bacillary Dysentery
43	21	7 (<i>E. hist.</i> + <i>lamblia</i> , 2; <i>Flexner</i> IV + <i>lamblia</i> , 1)	3 (<i>E. hist.</i> + <i>Sonne</i> , 1; <i>E. hist.</i> + <i>Flexner</i> I, 1; <i>E. hist.</i> + <i>Flexner</i> II, 1)	6 (<i>Flexner</i> untyped, 1; <i>Flexner</i> I, 1; 1; <i>V</i> , 1)

series with a larger series of 152 similar cases investigated at other R.A.F. hospitals in England; these patients had their specimens of stools examined but were not sigmoidoscoped. The incidence of pathogenic protozoa or bacteria in the large series was 4.5%. This marked difference in positive findings provides convincing proof of the value of sigmoidoscopy in sprue.

Summary and Conclusions

The sigmoidoscope is as necessary in the diagnosis of chronic dysentery as the microscope is in the diagnosis of chronic malaria.

The examination of three fresh stools passed in the laboratory annex after the administration of salts appreciably increases the number of positive findings in amoebiasis.

The sigmoidoscopic appearances were normal in 20% of positive cases of amoebiasis and in 9 out of 52 cases of chronic bacillary dysentery (2 cases of the total 52 were not sigmoidoscoped before treatment).

In 16 out of 53 symptomless cyst carriers of *E. histolytica* type lesions were seen in the rectum.

In 46% of Service personnel invalidated from the Tropics with a diagnosis of sprue or para-sprue pathogenic intestinal protozoa or bacteria were isolated from sigmoidoscopic swabs.

I am indebted to the Director-General of the R.A.F. Medical Service for his permission to publish this paper; to Sir Harold Whittingham for his helpful criticism; to the numerous medical officers of the R.A.F. for their loyal co-operation; and particularly Miss M. Sage and Sgt. A. G. Greenfield for their able assistance.

PREVENTION OF INFANT DEATHS

LIAISON BETWEEN HOSPITALS AND HOME SERVICES

BY

J. TUDOR LEWIS, M.D., D.P.H.

Medical Officer of Health, County Borough of Barnsley

he need for ensuring the suitability of the home to which it may be necessary to discharge a premature baby has been stressed by many authorities (Hess and Lundeen, 1941; Potter, 1944; Tyson, 1944; Crosse, 1945; Ministry of Health Circular No. 20/44). To what extent disregard of this precaution (which is as important for full-term babies and those convalescing from acute illnesses as for prematures) contributes to the number of preventable infant deaths is unknown, for while investigations into the ultimate fate of prematures are not uncommon (e.g., Brockington, 1944; Asher, 1946), the follow-up of babies, full-term as well as premature, in the first year after discharge from maternity unit or hospital seems to have been neglected. A hint of what an extensive survey might show is given, however, by Collis and Majekodunmi (1943), who traced 5 premature infants that had passed through their department: had died—two of these within the first month of discharge and four during the first year.

Attention was directed to this question while attempting to evaluate the efficiency of the infant health services in this area (Lewis and Blackwood, 1946). Of 31 infant deaths which were probably preventable, 7 might have been caused by discharging a baby (premature or full-term) to a household where conditions were prejudicial to the successful rearing of an infant. It has become a commonplace to speak of the importance of liaison between the hospital and the home. Like all platitudes its truth is obvious, but it happens that the attainment of really effective liaison is not as simple as would at first appear, for it raises clinical, sociological, and administrative problems that themselves have yet to be solved.

The purpose of this paper is: (i) to emphasize the need for effective liaison by describing case histories where its absence probably contributed to an infant's death; (ii) to discuss the respective points of view of the hospital and field worker and the principles underlying liaison; (iii) to suggest means by which liaison may be attained.

The Need for Liaison

The following cases illustrate the need for liaison and co-ordination of services, for in each instance death might have been attributable to lack of co-ordination.

Case Histories

Case 1.—Male, born Dec. 13, 1944, in maternity unit. One of triplets. Birth weight, 4 lb. 2 oz. (1.87 kg.). One baby died in hospital. Mother aged 26. One other child born, 1943. Normal pregnancy; W.R. negative. Hb, 66%; R.B.C., 3,700,000. Spontaneous delivery. Two surviving triplets discharged home on Jan. 10, 1945. Father (29 years old) in Forces. Home clean but overcrowded. Babies fed on breast complemented by half-cream dried milk. Lactation failed after about six weeks. The child seemed to be making good progress up to Jan. 29, 1945, but died on Feb. 8 of pulmonary congestion and bronchitis, being moribund when the doctor was called in. He thought that these babies would have been better for being retained a little longer in hospital than was the case.

Comment.—This mother had suffered from anaemia during pregnancy and had given birth to triplets. Although the home conditions were reasonably good the house was overcrowded and the mother had to cope with the two surviving triplets and the elder child of 18 months without the support of her husband, who was in the Forces. These babies should preferably have been retained in hospital until they were more firmly established.

Case 2.—Male, born Feb. 10, 1945, in maternity unit. Birth weight, 8 lb. 2 oz. (3.68 kg.). Mother aged 24; high-grade mental defective. One other female child, aged 2 years 9 months. Normal pregnancy; W.R. negative. Hb, 70%; R.B.C., 3,500,000. Spontaneous delivery. Discharged in satisfactory condition to very unsuitable home on Feb. 20, 1945. Father (31 years old) in Forces. Four people living in one small room not very clean and unfit for young baby. Breast-fed. In spite of these poor conditions the baby did well at first, but in a month or so began to deteriorate. When he was four months old he was admitted to hospital with pneumonia, and there remained for three weeks. He was discharged home, but was readmitted in a few days with an abscess of the back. He was subsequently transferred to another hospital, where he died, aged 6 months, of an abscess of the back and consolidation of the left base. He was also found to have an enlarged congenital heart.

Comment.—This baby was healthy at birth and thrived for the first few months in spite of a grossly unsatisfactory home environment. He should preferably not have been discharged to such home conditions, although it is difficult to see what the alternative could be. On discharge from hospital after pneumonia he should not immediately have been returned to the home conditions that probably had occasioned his admission.

Case 3.—Female, born July 24, 1945, in maternity unit. Birth weight, 7½ lb. (3.4 kg.). Mother aged 30. Two other children aged 10 and 3 years. Normal pregnancy. Hb, 60%; R.B.C., 3,700,000. Spontaneous delivery. Father aged 30. Family living with grandmother in council house. Home reasonably good. Mother developed breast abscess and baby then fed on one breast and complementary feeds. Discharged on 15th day and gradually went downhill. Baby readmitted to hospital on Aug. 13, 1945, where it died of marasmus on Sept. 4.

Comment.—This baby was healthy at birth and should have done well. On discharge from hospital the mother was not really fit. She had been anaemic during pregnancy and had had a breast abscess. Although the home conditions were reasonably satisfactory she had to handle two other children and a husband in someone else's home, and her mothercraft consequently was inefficient. It would have been advisable for this baby (and mother) to be retained in hospital a little longer until the mother was fit and the baby firmly established.

Case 4.—Female, born Aug. 8, 1945, in maternity unit. Illegitimate. Birth weight, 5 lb. (2.27 kg.). Mother 29 years old; works in chemical factory. Pregnancy normal, but she defaulted from the antenatal clinic from April to July. Spontaneous delivery. Discharged on 10th day. Mother and baby lived at two different addresses in the five-day interval between discharge from hospital and the death of the baby on the 15th day from bronchopneumonia. The first address was in an old, overcrowded house not very clean.

Comment.—A 5-lb. baby should with experienced care have survived, but should not have been discharged on the 10th day to unknown home conditions in the care of an inexperienced mother with no resources.

Case 5.—Male, born Aug. 8, 1945, in maternity unit. Birth weight, 5 lb. (2.27 kg.). Mother aged 26 years; first baby. Normal pregnancy; W.R. negative. Hb, 50%; R.B.C., 2,700,000. Spontaneous delivery. Discharged on 10th day. Father (aged 35) a miner. Clean home. Seen at infant welfare centre five days after discharge. General condition not good; frequent stools. On half-cream dried milk three-hourly. Readmitted to hospital on Aug. 27, 1945, where it died on Sept. 11. The family doctor stated that the mother was quite incapable of looking after the child, which was frail and difficult, and she had had no opportunity of learning to handle it.

Comment.—A baby of 5 lb. should survive with experienced care. The mother had been very anaemic during pregnancy, and on the 10th day was probably not feeling fit. She had had no experience of babies previously, and clearly the care demanded by a 5-lb. infant was beyond her capacity. The mothering it received during the first critical days after discharge from hospital was inadequate, and it never recovered from the setback it then received.

Case 6.—Female, born Aug. 18, 1945, in maternity unit. Birth weight, 5 lb. (2.27 kg.). Mother aged 35. One other boy, aged 10 years. Mother rather highly strung. Normal pregnancy, but with excessive sickness and general health not very good. Spontaneous delivery. Father (aged 36) a colliery deputy. Baby on breast and complementary feeds two-hourly. Died suddenly on day after discharge—aged 10 days. Necropsy: caillary bronchitis.

Comment.—It is at least possible that this baby was infected before discharge from hospital (although it showed no signs of this) and that it would have died in any case. But it is questionable whether a 5-lb baby should have been discharged on the 9th day in the care of a rather highly strung mother whose only other experience of child-handling was 10 years previously. If the mother and child had been retained in hospital, and arrangements made with the domiciliary services for the reception of the child at home and for instructing the mother how to handle it, it might have survived.

Case 7.—Male, born Sept. 10, 1945, in maternity unit. Birth weight, 5 lb. 4 oz. (2.38 kg.) Mother aged 22. One other child, 1 year old. Antenatal clinic attended regularly. W.R. negative. Hb, 58%; R.B.C. 3,500,000. Spontaneous delivery. Father (aged 23) a miner. Living conditions fairly satisfactory; no overcrowding. Discharged from hospital on the 9th day. Mothercraft not very good. Admitted to isolation hospital at age of 3 weeks for acute enteritis, but little abnormal found. Discharged two days later, but readmitted next day with vomiting; nothing found clinically. Died suddenly the following day. No necropsy.

Comment.—Although living conditions were reasonably good, the mother had been anaemic and her mothercraft was poor. She was incapable of caring for an immature baby as well as a child of 1 year in addition to a house and husband. The latest baby suffered. Although it would have been difficult to forecast the inadequacy of the care it actually received, it would have been better for remaining in hospital until more firmly established. When the child was admitted to the isolation hospital the diagnosis was doubtful, and an error of judgment was made in discharging it after two days. This might be understandable, but in any case it should not have been discharged to the conditions which probably brought on its illness.

Principles Underlying Successful Liaison

Clearly, the death of each one of these infants was caused, directly or indirectly, by the poor "mothering" and care it received after leaving the hospital or maternity unit. Premature infants who have done well in hospital and achieved a weight in excess of 5½ lb. (2.5 kg.) still need special attention and care. But it is not only the premature that need this care. Weakly or feeble infants, those convalescing from acute illnesses, and even those born healthy and robust will fail to thrive on leaving hospital unless the careful treatment they have been used to is maintained. It should not be overlooked that in hospital they became accustomed to expert attention, and the sudden change to the charge of a relatively inexperienced mother may be more than they can withstand. When returned to a good home with a capable and sensible mother such infants will do well. But when they enter unsatisfactory households they are exposed to a serious risk. This risk may be partly averted by making provision for the care of the mother and baby (or, where the child is older, of the baby alone) beyond the period when hospital care is strictly necessary, until the baby is firmly established or has recovered from its illness, while at the same time giving the mother an opportunity of learning how to care for and handle it.

The provision of such care is not easy. The best arrangement would be a hostel where mothers and their babies could be accommodated and where special instruction would be given in baby-care and mothercraft. A hostel on the lines described by Brodie (1946) would be suitable. For the moment this must remain an ideal, although it should have a place in the infant health services of the future. Where, therefore, such post-hospital accommodation is desirable it will usually be necessary to retain the baby in the hospital or unit. This raises difficulties, not the least of which is the availability of beds and cots. But undoubtedly the chief concern of hospital administrators and paediatricians would be the risk of cross-infection. This, of course, is a danger which would have to be faced in any *ad hoc* nursery or hostel for mothers and babies, although as many of the babies would have passed the neonatal period the danger would be rather less.

Parsons (1944) considers the risk of contracting an acute infectious illness to be much greater in an institution than in the home, and, while much will depend on the institution and much on the home, in general this dictum is unassailable. Where, then, do the interests of these infants lie? Is the potential danger of cross-infection in hospital greater than the hazard of grossly unsuitable home conditions? Whichever way lies the answer—and it is unlikely that any two cases will be similar—these dangerous alternatives must be carefully

balanced. The former is a problem in hospital administration; the latter in social medicine: if infants are not to die in no-man's-land that divides these two branches of medicine must be the closest understanding between the hospital practitioner and the field worker. If they are to find common ground the one must be aware of and understand the difficulties the other has to face and the problems which confront these difficulties and problems may briefly be considered.

Cross-infection In Maternity Units and Hospitals

Dealing first with cross-infection, the question most urgently needing an answer is, What are the chances of an infant being infected if he is retained in a children's ward or nursery? To this question, unfortunately, it is impossible to give an answer. According to a committee of the British Paediatric Association (1946) frequency, extent, and results of cross-infection in children's wards have never been ascertained. In the absence of such knowledge perhaps the most outstanding fact to be grasped is that the risk of cross-infection may be entirely fortuitous: "In spite of crowding and poor hygiene, one ward may for long be without manifest cross-infection, whereas another which has every facility and is staffed by well-trained nurses may suddenly be the scene of a virulent outbreak." Similarly, the seriousness of outbreak of infection in children's wards seems to be equally unpredictable: there is little means of foretelling how severe the infection will be. Outbreaks of so-called neonatal gastro-enteritis may have an alarming mortality, as described by Sakula (1943), when 20 out of 25 newborn infants died, and by Henderson (1943), who reported a mortality of 69% in immature infants. An estimate of the mortality from respiratory infections is not easy, owing to the difficulty of diagnosing pneumonia at this early age; undoubtedly a frank pneumonia or bronchitis would be attended by a high death rate even with modern chemotherapy. Skin infections usually take the form of a bullous impetigo, and the outbreak described by McFarlan (1942), Benians (1943), and Nisbet (1944) were mild, causing little anxiety apart from the worry inevitably connected with staphylococcal infections in nurseries. The use of the sulphonamides and penicillin has further reduced the risk of these staphylococcal infections of the skin, and it may be that dangers need not be exaggerated.

Adverse Home Conditions

It will be generally agreed that there is a positive correlation between a poor home environment and a high infant mortality. That there are specific and definable factors operating within homes or households is certain, but there seems to be little definite knowledge as to what exactly these factors are or what is their relative significance. Ryle (1946) has drawn attention to the logical aspect of this problem, and unquestionably its clarification is urgently needed. Reference is made below to an attempt to collect information which will do something to help in this direction. Without anticipating what will emerge from the inquiry, the preliminary findings indicate that the following are involved:

Conditions Affecting the Mother.—(1) Mental defect. (2) Low intelligence, but not amounting to mental defect—"mere feebleness." (3) Mental or psychological abnormality of the mother. (4) Maternal inefficiency; poor mothercraft and homecraft; lack of parental responsibility. (5) Chronic or subacute ill-health. (6) Unmarried girl with no friends or resources.

Environmental Conditions.—(1) Unhygienic, insanitary, or crowded housing conditions. (2) Lack of equipment. (3) Economic circumstances; insufficient income; mother having to go out to work. (4) Large family of young children, so that the mother cannot give enough attention to the latest baby. These factors can be added to, and it is usual to find several operating in a household, where they form a vicious circle. The amelioration of such conditions is extremely difficult, and in the light of experience so far gained may even be impossible; no attempt is made to do so with them here, although the urgency is self-evident. Such households are called "observation households," and it is of paramount importance that their existence be ascertained as early in pregnancy as possible and the potential danger to the expected infant assessed (Lewis and Blackwood, 1946).

These two subjects—the danger from hospital cross-infection and the hazard of the home environment—are the main matters of immediate importance to be discussed by the hospital doctor and the medical officer of health. But if the discussion is to stop at this point liaison would fall far short of the ideal. Where there is any question of the home environment affecting the well-being of a baby the clinician must be made aware of the child's background and the necessary information must be in his hands at the earliest moment. This is important; a real and permanent reduction in the infant mortality rate can be effected more readily by attending to the conditions in

which babies have to be reared than by studying their morbid pathology. Liaison should not be an end in itself but an integral part of the infant services, and it cannot be planned as a separate entity. Regard must be paid to these principles: liaison is to be effective.

Methods of Attaining Liaison

Through the courtesy of colleagues working in certain other areas I have had an opportunity of studying methods of attaining liaison there. In general, the usual practice seems to be for the maternity unit or hospital to inform the public health department of the impending discharge of a baby, to furnish a short report on the child, and to request, where necessary, or an early call to be made by the health visitor. It is no use carping criticism to say that such "liaison" could hardly be effective. The clinician is quite unaware of the home environment: a child may be discharged to grossly unsatisfactory home conditions, and irretrievable damage may be done before the health visitor calls.

With these thoughts in mind a trial scheme was introduced in this area, based on the principles stated above. It would be premature to describe its detailed working or the results to date, but after five months' experience it has worked well. It involves the following matters.

- (1) The unofficial reporting of pregnancies to the public health department by antenatal clinics and domiciliary midwives.
- (2) Following on (1), the early investigation of the social, economic, and environmental characteristics of the families and households into which a baby is to be born.
- (3) Based on (2), the ascertainment of observation households as early in pregnancy as possible and the maintenance in the public health department of a list of such households.
- (4) Attempts to counteract or ameliorate the adverse conditions discovered to be present in observation households.
- (5) The checking off of all birth notifications against the list of observation households, so that the birth of the baby into an observation household is known immediately it occurs.
- (6) Where the birth of a baby from an observation household (observation baby) occurs in hospital, an immediate written report of the home circumstances is sent to the hospital doctor, who is thus made aware of the home background.
- (7) When a baby under 1 year old is admitted to hospital for illness the fact is reported to the public health department. The baby is found to be from an observation household a report of the home conditions is sent to the hospital doctor.
- (8) When a baby from an observation household (either born in hospital or subsequently admitted) is considered to be ready for discharge, a discussion takes place between the hospital doctor and the medical officer of health with special reference to the question of cross-infection and the adverse home environment.

This scheme, here briefly described, is not devoid of administrative difficulties, but these can be ironed out. It places the onus for initiating liaison on the public health department, where it should rightly belong, and makes the medical officer of health responsible for reporting to the hospital when the home environment is not satisfactory—a function which is properly his. The problem of effective liaison is put in its right perspective; it is not regarded as a separate entity, but co-ordinated with the other aspects of the plan. It is hoped, moreover, by the ascertainment, investigation, and follow-up of observation families and babies to collect information which will throw light on those sociological factors known to maintain a high infant mortality rate. With the coming cleavage between hospital and domiciliary services it will be the more necessary for liaison and co-ordination to be placed on a solid basis.

Summary

The need for close liaison between maternity units and hospital home services, especially public health departments, is emphasized by describing case histories where lack of liaison might have resulted in an infant death.

The principles underlying effective liaison are discussed. There are households where the successful rearing of a baby is made precarious by specified adverse environmental conditions, and in such cases it may be necessary (pending the provision of suitable hostels) to retain mother and baby in hospital for a period. Such cases the risk of cross-infection must be balanced against the dangers of the home environment. In all such cases a full

report on the home conditions and environment should be supplied to the hospital doctor by the medical officer of health.

A trial scheme is briefly described by which effective liaison and co-ordination may be attained as an integral part of the infant health service.

OBSERVATIONS ON VASCULAR INJURIES

WITH SPECIAL REFERENCE TO THE VALUE OF SYMPATHECTOMY IN LIGATION OF MAIN VESSELS*

BY

A. M. BOYD, F.R.C.S.

Assistant Director, Surgical Professorial Unit, St. Bartholomew's Hospital

My experience of vascular injuries is limited to those cases reaching a base hospital in Egypt between October, 1942, and October, 1945, consisting principally of aneurysms. A few recent injuries of blood vessels due to local shooting and stabbing affrays were admitted, and there were a few secondary haemorrhages requiring ligation of main vessels.

Altogether 41 main arteries were ligated. With one exception every case was submitted to sympathectomy 14 days before or at the time of operation on the artery. Prof. Paterson Ross, at Hill End Hospital, for one reason or another ligated 15 main vessels, also preceded by sympathectomy. It is with the results of ligation of primary arteries that I wish to deal here. The solitary point I hope to make is that ligation of a main vessel should be accompanied by sympathetic denervation of the limb. Ligation of the main artery of a limb carries with it a considerable risk of gangrene. This is especially so in gunshot wounds because, as a rule, many collateral vessels are injured at the same time. Sir George Makins collected a series in the war of 1914-18 in which the primary artery had been ligated and the fate of the limb left to the collateral blood flow. The percentages of cases complicated by gangrene according to arteries involved were as follows:

TABLE I

Subclavian	..	25%	Femoral	..	25%
Axillary	..	16.6%	Popliteal	..	41.6%
Brachial	..	23%			

Averaging these cases, gangrene occurred in 26%. The popliteal artery is especially dangerous. Most surgeons would agree that ligation carries a risk of at least 40%, and many would assess the risk considerably higher. Apart from frank gangrene, depleted blood flow leads to ischaemic necrosis of muscles with crippling contractures, fibrosis, wasting of muscles, and nerve palsies. Even if these grosser manifestations are not seen, inadequate blood supply to the muscles is revealed in the lower extremities by intermittent claudication. The fate of the limb after ligation depends on the collateral circulation. Every effort must be made to expand it quickly. Blood pressure must be maintained by transfusion. The limb should be kept below the level of the heart by blocks under the head of the bed. The affected limb should be kept cool and the rest of the body warm to aid sympathetic release. The surest method of

* A short paper read before the Association of Surgeons of Great Britain and Ireland, May, 1946.

dilatation of the collateral circulation is by sympathectomy. It has been practised in America for many years. Gage and Ochsner (1940) have carried out sympathetic block in all cases of traumatic injuries to blood vessels, and in operations for aneurysm since 1930, without the occurrence of a single case of gangrene. British surgeons seem to be suspicious of sympathectomy largely because of the inability of physiologists to reconcile this procedure with the results of their researches on the experimental cat and dog. It has become the fashion to doubt the value of operations on the sympathetic nervous system. It has been stated that stimulation of the sympathetic leads to vasoconstriction in the skin but increased blood flow to the muscles, sympathetic block to increased blood flow to the skin but reduced flow to muscles. The points were stressed in a paper by Siddons (1945) condemning sympathetic block. There are, however, certain solid facts in favour of the value of sympathectomy: (1) In spite of the deductions of the laboratory worker in the experimental animal it is well known clinically that sympathectomy will improve intermittent claudication; (2) Theis (1933) has shown convincingly in animal experiments that sympathectomy increases the total in-flow to a limb and increases the collateral circulation after ligation of a main vessel. Barcroft and Edholm (1943) have shown that there are vasoconstrictor fibres to the blood vessels supplying muscles in man. There is, in fact, a weight of clinical and also some experimental evidence that sympathetic denervation improves the circulation to the whole limb—muscle as well as skin. Three cases of main-vessel ligation in forward areas without gangrene but with severe claudication were admitted to hospital: one patient with common iliac ligation, able to walk only 10 yards (9 m.) without cramp, one popliteal and one femoral ligation, all "claudicating" under 100 yards (90 m.). They were submitted to lumbar ganglionectomy and were able to walk half a mile (0.8 km.) on leaving hospital. I have ligated 41 main vessels. In 40 of them a sympathectomy was carried out either at the time of ligation or a fortnight before; most of them were not simple ligations but excisions of long segments. Twice I have performed triple ligation with excision of the common femoral, superficial, and deep femoral arteries. Next day, in both cases, the foot on that side was appreciably warmer than the other. The popliteal artery has been ligated and portions excised at all levels in its length. In this series there was one example of gangrene following excision of an arterio-venous aneurysm at the adductor opening. This man, an Italian P.O.W., had multiple wounds round the knee; many of the collateral vessels had been divided. Clinically the peripheral circulation in both legs was very poor. In the only case not submitted to sympathectomy in this series ischaemic necrosis of the forearm muscles occurred.

Traumatic False Aneurysm

Our experience of this condition is limited to 15 cases. It is usually stated that operation should be delayed for three months in order that a good collateral circulation may form. While this policy may be sound, it seldom seems possible. In my

TABLE III

Common femoral ..	3	Subclavian ..	2
Superficial femoral ..	2	Axillary ..	2
Popliteal ..	3	Brachial ..	3

series 13 out of 15 had to be operated upon before the optimum time because of external haemorrhage, progressive enlargement with threat of rupture, nerve compression, and in one case infection. Other surgeons have had similar experiences. I rather doubt the soundness of the policy of waiting for a collateral circulation to develop. A few arteriographs of aneurysms that I have made have not shown the characteristic tortuous vessels that are usually seen in arteriographs of main-vessel thromboses. The hypertrophied vessels that do form seem to be around and, in connexion with the sac, and are of necessity injured during operation. In two cases operation had to be carried out as an emergency for external haemorrhage between the second and fourth weeks while the aneurysm was

only just out of the pulsating arterial haematoma stage, much impressed by the ease of operation. Soft clotted mopped away and the vessel could be easily identified through the floor of the sac. Owing to the extreme culty of operation between the fourth and tenth weeks the fact that the surgeon's hand is so often forced by conditions to operate during this difficult period, I am persuaded that to operate upon them between the second and fourth is preferable to waiting until a later date. I do not but that the increased collateral circulation is worth waiting. Relief of tension by operation combined with vasodilatation sympathectomy should be adequate.

Arterio-venous Aneurysms

I have operated on 13 arterio-venous aneurysms of the I have only one observation to make about the diagnosis that is the extreme difficulty in deciding before exploration what vessels are involved. Complications necessitating

TABLE IV

Common femoral ..	2	Subclavian
Superficial femoral ..	3	Axillary
Popliteal ..	3	Brachial

operation are unlikely to occur in arterio-venous aneurysm and therefore it is possible to wait six months or longer before exploration. A quadruple ligation accompanied by sympathectomy was the routine procedure, with excision of the sac possible without damage to neighbouring structures. In case of arterio-venous aneurysm of the first part of the subclavian sympathectomy was impossible owing to adhesions around the apex of the lung. Ischaemic contracture of the forearm muscles occurred.

Late Results

Out of Prof. Ross's 14 cases in which leg arteries had been tied with sympathectomy 11 have been seen again more than six months after operation. In all cases nutrition of the leg was excellent. The patients could all walk at an ordinary pace for three miles (4.8 km.) without claudication. Four complained of claudication if they walked fast. In assessing late results insufficient attention has been paid to distal following ligation of a main vein (Ross, 1946), the symptoms of which have sometimes been misinterpreted as the result of arterial ligation.

Conclusions

If operation is planned for ligation of a main artery sympathectomy should be carried out.

If ligation is carried out in an emergency, sympathectomy should be done at the same time or as soon as possible afterwards.

In traumatic false aneurysm operation should be performed two to four weeks after injury, accompanied by sympathectomy.

The population increase of the Middle East is touched on in PEP in their recently issued pamphlet *Basic Problems in the Middle East*. Famine, war, and disease have for long been the most important limiting factors; in addition scarcity of water prevents habitation of many areas. Improved systems of cultivation, introduction of forestry in Cyprus, and the settling up of industries all contribute to raising the standard of living; but between beginning of this advancement and the point where raised standards themselves limit population growth there may be a period of overcrowding and all the suffering that ensues from it. That the problem is not insuperable seems indicated by the experience of Japan, where the population has greatly increased in recent decades without an appreciable depression of living standards. On the other hand the situation in India is grave indeed, as John Megaw pointed out in a letter to this *Journal* on June 1946. Detailed population studies are required for all these countries. In Sudan, for example, traditional methods of estimating population have given figures that in some areas may be inaccurate.

A CASE OF PRIMARY AGRANULOCYTIC ANGINA

BY

I. M. LIBRACH, M.B., B.Ch.

AND

R. G. CRONIN, M.B.

view of its comparative rarity, we feel that it is worth while porting the following case, which was treated by continuous transmuscular drip pentose nucleotide and oral sodium icleinate.

Case Record

A married fitter aged 30 was first admitted to hospital on ay 27, 1943, with a history of pains in the knees, ankles, and the 'elbow, wrist, and fingers of five days' duration. He was a oderate drinker and smoker. The previous history included an ack of rheumatic fever at the age of 7.

On examination his temperature was 100° F. (37.3° C.), pulse 80, spiration 22. He looked pale, but had no other gross physical gns. The urine was normal; the blood sedimentation rate was mm. in one hour. He was thought to be suffering from acute eumatism, and was given salicylates, with little or no effect. On ne 1 an ulcer of the gum was noted, and three days later several ore had appeared, with a lymphadenitis of the deep cervical ands. The white cell count was 2,400 per c.mm. (neutrophil ymorphs 17%, lymphocytes 69%, and monocytes 14%). aemoglobin and red cell count were normal. He was given 1 ml. of pentose nucleotide daily for three days, after which the hite cell count remained the same, but the neutrophils had risen 28% and there were 2% myelocytes. On June 11 he was feeling ater, the ulcers had gone, and he was afebrile, but the white ils had dropped to 1,900 per c.mm. (neutrophils 22%, lympho- tes 69%, monocytes 9%). Pentose nucleotide, 60 ml. daily, was ven for three days, and on the last day he was transfused with a nt of Group B whole blood, three days old. On June 14 there as no change in his total white cell count, and a marrow puncture ive the following result:

Cell Type	%	Range of Normal Values (%)
ro-erythroblasts	4.0	0-4
rythroblasts	16.5	2-7
onoblasts	1.0	7-19
ature polymorphs	13.5	20-50
asophils	0.5	0-1
asimorphs	1.0	0-4
yeloblasts	6.0	0-2.5
lyelocytes	11.0	2-9
ter immature polymorphs (metamyelocytes)	36.5	2.5-14.5
ymphocytes	10.0	5-20

he patient was anxious to go home and was discharged. The last hite cell count was 2,750 per c.mm., neutrophils 17%.

On March 2, 1944, after nine months at home, he was re- dmitted with similar symptoms and signs. He was again dis- charged after being given low doses of pentose nucleotide, the white ell count showing no gross change. He was again admitted on uly 14 with a severe recrudescence of symptoms, especially the int pains. The white cell count was 3,150 per c.mm., neutrophils 6%. At the suggestion of one of our colleagues (Dr. Marchmont) continuous intramuscular drip containing 40 ml. of pentose ucleotide in 540 ml. of normal saline was given into the vastus ternus at the rate of ten drops a minute, and was continued for hree days, 120 ml. of pentose nucleotide being given in all. A hite cell count then showed a total of 6,700 per c.mm.; the nucle- ide was, however, continued by the intermittent method, 10 ml. eing given intramuscularly twice daily for three days, and 5 ml. wice daily for a further three days, but the count remained the ame. A further 5 ml. once daily for three more days was ordered, and on the completion of this course the white cells numbered 1,500 per c.mm.

Further investigation showed that the haemoglobin percentage, red blood cell count, and platelet count were normal, having remained o throughout his illness. A fractional test meal revealed low cidility, with some delay in emptying of stomach. Biopsy of an uillary lymph gland showed marked reactive hyperplasia of lymph erm-centres and reticulo-synctium.

Between July 31 and his discharge on Aug. 12 no further nucle- ide was given, but the white cell count remained around 6,500 per c.mm. On the analogy of the replacement therapy of Addison's aemia, sodium nucleinate in doses of 1 to 2 dr. (4-8 g.) daily was given, and in the subsequent follow-up at the out-patient department o significant change in the count was noted after ten months. The

oral nucleinate was therefore stopped, and up to the time of writing the count has remained within normal limits.

Discussion

Speculation has been rife on the aetiology of this disease, and many theories have been put forward. Rutledge *et al.* (1930) believe that the condition is a primary disease of the myeloid tissue of the marrow and that the necrotic ulcerations are produced as a result of the neutropenia allowing of bac- terial invasion. Osgood *et al.* (1939) quote the normal white cell differential count as follows:

Cell Type	No.	Range %
Neutrophil	1,500-7,500	15-75
Eosinophil	0-400	0-4
Basophil	0-200	0-2
Lymphocyte	1,000-4,500	10-45
Monocyte	0-800	0-8

When our own case was first suspected on June 4, 1943, the patient had 408 neutrophil polymorphs per c.mm. of blood, and the marrow film count, on June 14, 1943, showed a clear majority of young immature cells of the prematuration series, suggesting the maturation rather than the aplastic type of the disease. His relapses in March and July, 1944, suggest a critical level of 1,500 neutrophil polymorphs per c.mm. below which symptoms and signs are observed. Of course, this critical level, below which stomal ulceration may occur, possibly varies from patient to patient. The following case is an example.

A boy aged 10 was admitted with ulcers on the buccal mucosa. The white cell count was 4,600 per c.mm., of which 59% (2,750) were polymorphs and 38% lymphocytes. He had had 12 g. of sulpha- thiazole. Was he suffering from sulphonamide granulocytopenia with a critical level above that of the other case? Whitby maintains that the polymorph counts in children approach the adult level one week after birth. Within eleven days this child's white blood cell count had risen to 9,000 per c.mm., of which 50% (4,500) were polymorphs.

The stimulus which causes granulocytes to enter the circula- tion is said to be nucleic acid and its derivatives, though its role in maturation is uncertain. Again, pentose nucleotide is said to be useful in both primary and secondary granulocyto- penia, the usual method being by daily intermittent intra- muscular injections; but though our patient had 105 ml. by this technique his white cell count only slowly improved. A transfusion of a pint of blood made no appreciable difference. However, the value of blood transfusion in these cases is dis- puted, the only effect, theoretically, being to add nucleotide to the patient's blood by the breakdown of donor leucocytes. Whitby and Britton (1944) state that the total white cell count may actually be lowered as a result of transfusion. It occurred to us that failure may have been due to too rapid destruction of the nucleotide or the overstimulation of the marrow by one massive dose. We therefore thought that a continuous intramuscular drip transfusion, of a total of 120 ml. of nucle- tide in saline, at the usual rate of ten drops a minute might be better. The total white cell count rose in three days from 3,150 to 6,700 per c.mm. at a much greater rate than that obtained with the intermittent injections of 105 ml. of nucle- tide for a further nine days.

The question remaining unsolved was whether he might recover in any case (as these cases sometimes do). On Jan. 1, 1946, after he had been ten months off sodium nucleinate, his white cell count was 6,400 per c.mm. This would seem to indicate a spontaneous recovery and the uselessness of the oral nucleinate, possibly because, unlike the haemopoietic prin- ciple, it never reached the marrow in an unmodified state, it being thoroughly digested in the gut beforehand. Glutathione and liver extract were never given, as the rationale of their use is doubtful, though the haemopoietic principle in the latter has some influence on white cell maturation. The patient gave only a five-day history when first seen, though whether this was really the first attack of his present malady is, of course, debatable. Finally, though neutrophil granulocytes were always present—i.e., the condition was a granulocytopenia rather than an agranulocytosis—we labelled it primary agranulocytosis, as most authorities, such as Wintrobe (1942), Whitby, etc., con- sider it the term best fitted to cover what is, after all, a very heterogeneous group.

Reviews

BIOLOGICAL EFFECTS OF RADIATION

Actions of Radiations on Living Cells. By D. E. Lea, M.A., Ph.D. (Pp. 402; illustrated. 21s.) Cambridge: The University Press. 1946.

Since the first use of radiation as a means of producing biological effects, both desirable and undesirable, there has been only a limited body of information available by which the worker with radiation could attempt to explain or understand its action. In this clearly written and thought-out work the author surveys the hitherto uncharted field of the immediate effects of radiation. Moreover he publishes charts which enable the serious worker to continue the exploration for himself.

Remembering that Lea has concerned himself with effects on visible structures on which experimental evidence is available and has only skirted the swamps of conjecture surrounding the more diffuse effects of radiation, we must admit that he has succeeded admirably in his aim. He starts by discussing the radiation and its physical properties, providing figures which must have required prodigious work to collect, and which form a basis for the detailed understanding necessary for all research workers in the subject. He goes on to discuss the chemical effects of radiation in an essentially quantitative way, based on the physical properties of the radiation and the ions which they produce and their relation to the aqueous medium in which their energy is absorbed. He then deals with the target hypothesis and its limitations. He considers its validity "unquestionable in the case of the inactivation of small viruses by radiation and the production of certain chromosome aberrations in higher cells," and "highly probable in the killing of larger viruses and bacteria and the production of gene mutations." He states that it is inapplicable to changes brought about by circulating blood or intra- or extracellular fluids affected by the radiation.

Lea specifies three types of investigation necessary to determine the applicability of the target theory to any given biological action—viz., the relation to dose, to dosage rate, and to the nature of the radiation—and lays down three corresponding criteria—viz., the survival curve is exponential, the effect is independent of dose rate, and the effect of gamma rays, hard x rays, soft x rays, neutrons, and alpha rays for a given dose decreases in that order. He provides graphs and figures which enable the investigator rapidly to determine target size from his own experimental results, and in subsequent chapters applies his criteria with such effect as to prove to our satisfaction that his statements quoted above are a true estimate of the position. The discussion of the effects of radiation on chromosomes is given in great detail.

No worker in the field of radiation should remain unacquainted with the contents of this book, though for the medically trained the physical and mathematical aspects may be too advanced for complete understanding. There is no doubt that this work is a masterpiece of clear and original thought applied to a most intricate subject, and that it will be considered in time as a classic work. It is to be hoped that Lea will bring the same power and energy to producing a similar work on other aspects of radiobiology hitherto unexplained. Explanation of the action of radiation brings us nearer to an understanding of the fundamentals of life.

PSYCHOLOGICAL TESTS

Manual of Diagnostic Psychological Testing. II. Diagnostic Testing of Personality and Ideational Content. Review Series, Volume III, No. 1. By David Rapaport, Ph.D., and Ray Schafer, B.S., with the collaboration of Merton Gill, M.D. (Pp. 100; illustrated. \$0.75). New York: Josiah Macy, jun., Foundation.

This is the second part of a survey of psychological tests and is concerned with a review of the word association, Rorschach, and thematic association tests. These are tests of personality, of the way in which the subject approaches problems and the underlying impulses and conflicts which determine such approach. Each test is described in detail and its purposes are discussed. The methods of administration are described and the pitfalls in interpretation recorded. The results are then

set out in various groups such as schizophrenics, depressives, neurotics, and normals.

The authors point out how the same sort of tendencies may be recognized through a series of tests, and make a plea for the use of a battery of tests instead of relying on single tests. They claim that it is possible in this way to distinguish between psychotics and neurotics and normals with a fair degree of certainty and, with sufficient care and variety of test, between preschizophrenics, depressives, and paranoids. It is obvious that if the promise of such distinctions can be maintained and extended it will have most important repercussions on medicine, especially in its preventive aspects, on vocational guidance, and in many other branches of social science. The present volume therefore merits close attention as a record of what has already been achieved and as a stimulus to further work.

DISORDERS OF INNERVATION OF PHARYNX, LARYNX, AND OESOPHAGUS

Les Troubles de L'Innervation Pharyngo-Laryngée et Oesophagienne. By Prof. F. J. Collet. (Pp. 320; 22 figures. 300 francs.) Paris: Masson et Cie 1946.

The innervation of the pharynx, larynx, and oesophagus, though well understood in broad outline, has always given rise to perplexities and apparently paradoxical phenomena in matters of detail, which have at times been the grounds of heated dispute. Prof. Collet in his recently published book on the disorders of innervation of the pharynx, larynx, and oesophagus gives in great detail the fruits of half a century of careful observation and profound study of these questions. If he has nothing original to say he at least presents these questions in full detail to the reader and avoids that over-simplification which is often thought sufficient but provides a very imperfect understanding of the subject. Clinical studies and case reports naturally figure largely in such a review, and the author is still inclined to rely rather on a description of syndromes than to elucidate the underlying processes or lesions which cause the syndromes. He therefore dismisses rather lightly the plea made by Burger some ten years ago for the abolition of eponymous syndromes and the substitution for them of a system of groups of paralyses at different levels based on a rigidly scientific anatomical localization. The eponymous syndromes have in fact of themselves no anatomical basis, with the exception of that of Tapia and possibly of Avellis, and are modifications of the group of associated paralyses originally described by Hughlings Jackson; and they have the further disadvantage that the different varieties are difficult to remember by their authors' names. This comment is made in order to illustrate the conservative attitude of Prof. Collet to his subject, but he has omitted no detail in his description, and, as the borderland of neurology and laryngology is the territory concerned, his book is of interest to specialists in those branches as well as to those who practise general medicine.

SURGERY FOR DENTAL STUDENTS

Essentials of Surgery for Dental Students. By J. Cosbie Ross, M.B., Ch.M., F.R.C.S. (Pp. 284; illustrated. 20s.) Edinburgh: E. and S. Livingstone.

The curriculum for the dental student requires that he shall have some knowledge of general surgery and especially of that of the head and neck. To gain this from study of the medical student's textbook of surgery is a very unsatisfactory method of procedure, not only on account of the difficulties of picking out the essential parts but also because the detailed descriptions often goes far beyond that which the dental student wants. The need therefore arises for a smaller textbook dealing with those aspects of surgery which are of interest to the dentist in just such detail as he requires. This need appears to be adequately met in Mr. Cosbie Ross's *Essentials of Surgery for Dental Students*. The author, who is lecturer to dental students in the University of Liverpool, is evidently very well acquainted with the type of teaching which the dental student appreciates. The whole of the matter is of course quite orthodox, but it is clearly laid out with appropriate headings in heavier type. The illustrations deserve special praise—they are exceptionally good, much to the point, and the reproduction is perfect; as the author says in his preface, "In the confident belief that our

good diagram is of more value to the student than pages of print, I have attempted to illustrate all important diseases." We feel sure this book will become very popular among dental students; it is excellently produced by the publishers.

CARE OF PATIENTS WITH VENEREAL DISEASE

Public Health Nursing in Syphilis and Gonorrhoea By Evangeline Hall Morris. (Pp. 240. 12s.). London: W. B. Saunders Comp. Co. 1946.

The title of this book may seem a little strange to the British reader since we have no one in this country who corresponds exactly to the American public health nurse; perhaps "the nursing and welfare of patients suffering from venereal disease" would describe its contents more effectively. The book starts with some account of the problem as it presents itself in the U.S.A. and goes on to relate the history and describe the signs and symptoms, diagnosis, and treatment of the two main venereal diseases; there follow chapters on the patient's needs, epidemiology, the organization of V.D. clinics, a description of the various agencies which deal with the problem, education of the individual at various ages, and finally an account of the duties of the public health nurse.

The clinical sections contain all that a nurse or nursing orderly need know about V.D., though it is news to be told that the gonococcus is anaerobic; most readers will be more interested in the later chapters, particularly those on sex education and the duties of the nurse. The author evidently knows what she is talking about, and those who were privileged to see American public health nurses at work in England during the war were greatly impressed with both their methods and the results they obtained.

All who have to deal with the V.D. patient and his problems, whether doctors, nurses, almoners, or social service workers, will profit from a study of this excellently produced little book.

A SURGEON'S AUTOBIOGRAPHY

Talk of Dreams. An Experiment in Autobiography. By Kenneth Walker. (Pp. 219. 10s. 6d.). London: Jonathan Cape. 1946.

Mr. Kenneth Walker in this latest work has provided us with an interesting, entertaining, and thought-provoking work. He takes his autobiography as far as the end of the 1914-18 war, judging that more recent events have not yet got into proper perspective. His theme is that only very occasionally has he been able to see himself or the universe of which he is part as a whole, and much as he dislikes the conception of psychological determinism he is forced to the conclusion that almost always his behaviour has been determined by four characters within himself largely founded on boyhood fantasies: "Black and white," the Red Indian brave who is impervious to hardship or pain; "Selous," the intrepid explorer always seeking some new thing; "Knight-Paton," the chivalrous knight-errant-missionary; and "Personage," the rather snobbish seeker for reflected distinction to be derived from association with the very important persons of this world. This is a quartet which many might recognize in themselves. Mr. Walker describes certain high-lights in his life and the reactions of his four inner actors in these circumstances.

A schoolboy at the Leys, an undergraduate of Caius, and a medical student at Bari make the setting. An expedition to Iceland, an ascent of the Matterhorn and of the Rothhorn, a thunderstorm, big-game hunting in East Africa, and six months in India are special high-lights. Next, five years of practice in Buenos Aires in an attempt to make money enough to escape from medicine; but then the Great War. This culminates in Walker's work in the forward areas, which was of the greatest value but which unfortunately for him never quite came to the fruition it deserved. The reviewer, who was also there, can vouch for the author's description of the disaster of Thompson's Cave on the third night of the Battle of Arras, which deprived him of the first forward operating set-up in the history of warfare, which has borne such great fruit in a later war. Nevertheless perhaps Mr. Walker gives too scanty a raise to the New Zealand tunnellers, by whose exertions 400 badly wounded men were got out of the cave without further casualties. Some of us less under the influence of "Knight-Paton" at that time envied and rather wondered at Kenneth Walker's apparent delight in mixing himself up with air-borne metal which we so cordially disliked. Now we know—or do

we? Clearly this book needs a sequel: we want to know how these characters have mellowed and co-operated to develop Mr. Walker's more philosophic ego of recent years. May he be persuaded to round off this admirable contribution to psychological literature by further conclusions on the vexed question of determinism and free will and the construction of the personality.

Notes on Books

In the fifth edition of H. M. TRAQUAIR's *Introduction to Clinical Perimetry* (Henry Kimpton; 36s.) anatomical names have been revised to conform to current usage. There are ten new illustrations. The text has been amplified to include experience gained in injuries seen during the war.

A second edition of R. M. HANDFIELD-JONES's *Surgery of the Hand*, which we reviewed favourably in 1941, has now been issued. The book has been enlarged by the addition of short chapters on amputations and burns, and there are new paragraphs on the use of penicillin in various types of infections. There are also a few fresh illustrations chiefly related to the new matter. The new edition retains the attractive format of the first. It is published in Edinburgh by E. and S. Livingstone at 20s.

The full text has now been published as a booklet (London: Christopher Johnson, Ltd.; 5s.) of Sir ARTHUR MACNALT's Thomas Vicary Lecture for 1945 on *The Renaissance and its Influence on English Medicine, Surgery, and Public Health*. A shortened version appeared in these columns on Dec. 1, 1945. Sir Arthur gives a description of the times in which Thomas Vicary lived, and of the sovereigns, statesmen, scholars, physicians, and surgeons of his day, with reproductions of Holbein's famous picture of Henry VIII granting the Act of Union to the Barbers and Surgeons and of his drawing of Sir Thomas More at the age of 50, from the Royal Library at Windsor Castle.

In *The Health of the School Child* Miss GERTRUDE E. CROMWELL (W. B. Saunders Company; 12s. 6d.) describes the general plan for school health work with particular emphasis upon the part to be played by the school nurse. She wisely sees the school as a unique opportunity for inculcating healthy habits and regards health education as something which can be best carried out with the child. American methods and outlook differ in some respects from the usual British standards, but this book should certainly be read by those responsible for the school health service in this country.

James Woolley and Co., Ltd., have issued a commemorative booklet entitled *Woolleys of Manchester*, being a record of 150 years in pharmacy. The firm was established by R. H. Hargreaves in 1796 and the business was acquired by James Woolley, who started as a medical student but was advised by John Dalton to make pharmacy his career, because he could not bear to witness the major operations, which were performed without anaesthetics. On the formation of the Pharmaceutical Society of Great Britain in 1841 James Woolley became one of its first members and took a leading part in the promotion of a Manchester branch. His great-grandson, Mr. G. S. Woolley, is now vice-chairman of the board of directors.

L'anémie infectieuse, by G. HEMMELER (Basle: Benno Schwabe and Co.; Swiss fr. 5), is a reprint of the author's researches on the anaemia of infection. The methods used were examination of the blood and the bone-marrow and estimation of the serum iron. Dr. Hemmeler concludes that the anaemia is of a hypoplastic type, due to toxic depression of the marrow. The serum iron is low during infection, but there is no reason to believe that the anaemia is due to iron deficiency. Owing to the isolation of Switzerland while the war lasted there are no references to American and English work during the last five years. Nevertheless, the author is in harmony with the American and English workers in believing that the intestinal epithelium plays a vital part in controlling the absorption of iron, and that in infection absorption is shut down.

American methods of heating would make it possible to provide heat throughout the whole of one of our houses for 24 hours a day for about the same amount of fuel as was used before the war by open fires in warming a small part of the house. This is one of the conclusions of a joint party from the Ministry of Fuel and Power and the Building Research Station and Fuel Research Station of the Department of Scientific and Industrial Research after spending nearly three months of the winter of 1944-5 studying heating, cooking, and hot-water supply in small houses in the U.S.A. and Canada. H.M. Stationery Office has now published (price 3s.) a report, *Domestic Heating in America*, which was prepared by the party on its return. This gives a comprehensive picture covering climatic conditions, fuel resources and costs, heat demand, distribution and maintenance of appliances, the relation of heating to house planning, smoke abatement, descriptions of heating, cooking, and water-heating appliances, chimneys, and heat insulation.

Nova et Vetera

ANCIENT MEDICAL TREATISES

Omar, he tells us, often wondered "what the vintners buy one-half so precious as the wares they sell"; and in much the same spirit is the wistful preface by Mr. J. I. Davis to the first post-war catalogue of medical and scientific desiderabilia issued by his firm (Davis and Orioli, now in Maddox Street, W.), hinting that he would like to keep rather than to sell his delectable wares and apologizing for the high prices which market trends have dictated. It really is a remarkable assembly of rarities which is here catalogued, and it is feasible to indicate only the most covetable of mouth-watering items—not always, by the way, the most expensive. Aretaeus of Cappadocia is represented by the second edition of a pamphlet (Paris, 1554) at £8 10s.: his claim to fame is that he was the first to give a full description of diabetes, and he probably had some knowledge of cardiac auscultation. Then there is a first edition of Francis Bacon's *Instantatio Magna* (1620), to which science is indebted for the exposition of inductive reasoning; this seems very reasonable at £65. Very precious, too, is the textbook on anatomy by Jacob Berengarius da Carpi (Bologna, 1521) which is priced at £350: it is one of only eight known copies, most of which are in public libraries, and is the first and only edition. Berengarius was the leading authority until Vesalius eclipsed him. A translation into English by H. Jackson, published in London, 1664, of another of this anatomist's works is listed at £75; only about four other copies appear to exist. Bernard of Gordon, believed to be a Scot, who taught medicine at Montpellier in the thirteenth century, is represented by a treatise on medicine (Lyons, 1491), priced at £110: in it he describes plague, phthisis, epilepsy, scabies, erysipelas, leprosy, trachoma as contagious diseases, so clearly he had got beyond the demoniac conceptions of most of his contemporaries. Sir Thomas Elyot's *Castell of Health* is offered in an edition of 1559 (at £22 10s.)—of enhanced interest because it belonged to Edward Fenton, Frobisher's navigating officer, and one who took part in the defeat of the Armada. The treatise of Ferrerius on syphilis (1564, £12 10s.) recommends sarsaparilla for the "Spanish disease." The first edition of William Gilbert's book on magnetism (London, 1600) has an interest far outside medicine, of course; it does not seem dear at £105. The third edition of Harvey's *De Motu Cordis et Sanguinis* (Leyden, 1639) is priced at £68 (until recently it was thought to be the second edition); and the first edition (1651) of the *De Generatione* at £60. Extremely rare is a popular English digest of Hippocrates, published in London, 1530, one of about half a dozen copies, offered at £145. Ulrich von Hutten's book on the use of guaiacum in the treatment of syphilis—from which the author himself suffered—published at Strassburg in 1519, costs £75; whereas £130 is asked for the first edition of Jenner's classical treatise on smallpox and vaccination. An edition, believed to be the fourth, of John de Gaddesden's *Rosa Anglica*, which runs to over 1,200 pages (1595), can be got for £21, whereas £350 is the price of John de Ketham's *Medicine*, Venice, 1500: it is supposed to be the work of Johannes Kellner, professor at Vienna, 1445–70, and contains woodcut illustrations never previously equalled. Laennec's first account of auscultation (Paris, 1819) is quoted at £35. Then there are three medical works by Jean Paul Marat, the French Revolutionary celebrity—incidentally Messrs. Sotheby were selling by auction on Oct. 14 a collection of a number of his writings. Ambroise Paré is represented by the first edition (Paris, 1564, £185) of his magnum opus on surgery—only two or three copies exist; and also by his book on plague and other topics (1582, £150). Peyer, of the patches, a Swiss anatomist, is the author of the book announcing his discovery published at Schaffhausen in 1677 (£27 10s.). An edition of Roesslin's *Midwifery* (Paris, 1538, £55) is of great rarity: it was the source-book of Raynalde's *Byrthe of Mankynde* (1545). There is space only to mention three or four items by Vesalius: perhaps of greater surgical interest is a book by Volkmann in 1875, annotated by Lister himself, who praises the author for having so fully comprehended the antiseptic doctrine. This is on sale at 4 guineas.

A further rarity deserving mention was to be sold, on the same day as the Marat pamphlets mentioned above, at Sotheby's Rooms. It is *The Treasur of Health* by Pope John XXI, translated by Humphrey Lloyd and published in London about 1550 by William Coplande: only one other copy is known to bibliographers, so keen competition was natural enough, and it fetched £65. At a further sale on Oct. 28 at the same Rooms a small medical library was catalogued: most of the items are of moderate rarity, but there are a few exceptions, such as Celsus, *De Re Medica*, Lyons, 1554; Dioscorides, *De Medicinali*, Venice, 1538; Glisson, *Anatomia*, Amsterdam, 1659; Harvey, *De Generatione Animalium*, Hague, 1680; Roesslin, *Ghestande Artzneybuch*, Frankfurt, 1590; Alexis of Piedmont, *The Secrets* (English translation), 1578.

CHARLES BATEMAN, CHIRURGEON: EXECUTED FOR HIGH TREASON, 1685

Macaulay has noticed the trial and execution of Bateman, a surgeon, in his *History of England*. A man of this name was apprenticed at Barber-Surgeons' Hall in the year 1651–2 to Thomas Bell, surgeon, and is almost certainly the man in question. *The State Trials* (Hargrave's Edition, 1776) gives an account of the proceedings.

In the first year of King James the Second Charles Bateman was tried at the Old Bailey on Dec. 9, 1685. He was accused of conspiring to bring about the death of the late King. In the first instance he asked for a postponement of his trial, but was told by Mr. Recorder (Sir Thomas Jenner) that he must plead before he could be heard. The indictment was read and Bateman pleaded not guilty. He said he had been kept a close prisoner for ten weeks, was much indisposed, and had had neither notice nor panel of jury. After some discussion he was allowed pen, ink, and paper, and his son to assist him. It appears that his residence was in the parish of St. Dunstan's in the West, in the ward of Farringdon Without.

Mr. Phipps, Counsel for the King, opened the case and was followed by Mr. Serjeant Selby and Mr. Charles Moloy. The prosecution's first witness, Josias Keeling, swore to having been at divers meetings at which methods were discussed. Rumbold*, since executed for high treason, was present at one of them; a discussion took place on a design to divide the City into twenty parts, to raise 500 men for each part, who were to be under one chief with nine or ten subordinates. Bateman said that the evidence of this witness contained nothing against himself, and this was allowed by the Court. Thomas Lec swore to the plan to divide the City as mentioned above and stated that Bateman had been nominated as manager of one part, his particular task being to try to obtain possession of the Tower. To this Bateman replied that had he been conscious of what was laid to his charge he was fit for Bedlam. Richard Goodenough gave evidence that Bateman had promised his assistance to a design to seize the City in connexion with the Duke of Monmouth's rebellion.

Bateman seems to have relied on endeavouring to show that the witnesses for the Crown were not to be depended upon; and the Court seems to have allowed that Goodenough, who had previously been pardoned, was not a creditable witness. The Lord Chief Justice (Jeffreys) summed up impartially and the jury found Bateman guilty. He was executed at Tyburn on Dec. 18, 1685.

In the Remarks on the Trial it is stated that Bateman was reputed to have been chirurgion to the Earl of Shaftesbury; that he had attended Oates after his whipping and had let him blood. That infamous scoundrel Titus Oates was sentenced to be whipped at the cart's tail from Aldgate to Newgate, and after two days' interval to be whipped from Newgate to Tyburn. It may have been after the first whipping that Bateman attended him. One would have thought that he would have lost enough blood to have rendered any further phlebotomy unnecessary. It is a fact that both parts of the whipping were carried out.

Mr. Le Fanu informs me that Charles Bateman's son, Richard, was apprenticed at Barbers' Hall on April 9, 1678, for seven years.

THE MENACE OF BLEACHED FLOUR

One of the most remarkable developments in the long struggle for wholesome and nutritious bread is reported by Sir Edward Mellanby at page 885 of this issue. In his laboratory dogs given a diet consisting largely of flour which had been bleached by the "agene" process invariably developed hysteria. Control animals fed upon the same diet but with unbleached flour remained free from this syndrome. For about twenty years canine hysteria has presented a problem which is as interesting to the pathologist as it is distressing to the dog-owner. Those familiar with the dog's sidelong glances at some unseen terror, the frightened barking, and the aimless rushing round which precedes exhaustion will appreciate the accuracy of Mellanby's description. Various authorities have ascribed his condition to factors as diverse as the after-effects of distemper, worms, ticks, or even a perverted appetite for gravel. For some time, however, enlightened veterinarians have concluded that more often than not hysteria in dogs is nutritional in origin.

It has long been known that certain wheat products are liable to cause this hysteria. Dog-biscuits and meals manufactured under excessive exposure to heat have been especially suspect. There has been difficulty, however, in deciding whether the trouble was due to a toxic factor or to deficiency of some essential nutrient. Melnick and Cowgill¹ found that their dogs had hysteria when given diets containing gliadin, the alcohol-soluble fraction of wheat gluten, and they considered that protein sensitization was involved. Arnold and Elvehjem² thought that the syndrome was attributable to deficiency of the amino-acid lysine, though Wagner and Elvehjem³ later discarded this view in favour of the theory of a toxic agent. Mellanby's new finding seems to indicate that the toxic substance is not present in the natural wheat but is formed by the action of the bleaching agent, which in the "agene" process is nitrogen trichloride. This and other processes have been widely used here and in America to bleach flour and improve its baking qualities. It is therefore likely that wheat products found to be toxic by previous workers have been submitted to similar treatment.

Attempts to elucidate the nature of the toxic substances are being made. Mellanby intends to find out, and it will be of crucial importance to know, whether wheat gluten, like flour, acquires toxicity only after bleaching. Meanwhile it is interesting to speculate on the possible mechanisms by which such a trustworthy food as wheat can become poisonous. The most important constituent of wheat gluten is glutamic acid, which makes up as much as 43% of the total amino-acid content. There seems little

reason to suspect injury from this direction. Indeed, Price, Waelsch, and Putman⁴ have claimed that *dl*-glutamic acid hydrochloride is a useful drug in the treatment of patients suffering from petit mal and psychomotor seizures. As Mellanby has pointed out, however, chlorine may act upon the tyrosin and tryptophane groupings of the gluten complex, and it is possible to visualize the formation of toxic bodies in this way. Kodicek, Carpenter, and Harris,⁵ for example, have shown recently that indole-3-acetic acid (heteroauxin), a substance related to tryptophane, may in certain circumstances have an adverse action on rats.

Mellanby's observations have been confined to the effects of the bleached whole flour. If the American work on the toxic properties of wheat gluten were unknown it might well have been assumed that these effects were due to the destruction of vitamins. Vitamins are present in such minute amounts that in many instances they are selectively attacked by the relatively small amounts of chlorine used in bleaching. They therefore suffer far greater damage than would be the case if the chlorine distributed its action evenly over all the components of the flour. In particular it might have been thought that the hysteria resulted from a destruction of adermin (vitamin B₆). Chick, El Sadr, and Worden⁶ found that rats deprived of this factor developed epileptiform fits which were obviously very similar to hysteria in dogs. Wagner and Elvehjem were unsuccessful in a single attempt to prevent hysteria by giving vitamin B₆, and Mellanby's dogs developed hysteria even though their diet contained yeast, a rich source of this vitamin. Against these findings we may place the experience of some veterinarians, who find that hysteria is often amenable to treatment with yeast. While awaiting further experimental developments it may be premature to exclude completely the possibility of dietary deficiency. Even if it is proved that wheat gluten becomes toxic after bleaching it is still possible that it may exert its injurious action by interfering with the absorption or metabolism of adermin. For this hypothesis we have a parallel in the work of Boas⁷ on the increased demand for biotin in rats given avidin in the form of unboiled egg white.

Whatever the true explanation of the action of bleached flour may be, it is clearly undesirable that food unfit for dogs should be eaten by the human subject without at least a full realization of the dangers involved. Perhaps some comfort may be drawn from the different response to wheat products shown by different species. Wagner and Elvehjem were unable to detect fits in rats, guinea-pigs, monkeys, and chicks feeding on sufficient wheat gluten to cause hysteria in dogs. As yet we have little, if any, evidence that diet is a significant factor in human epileptiform fits, and the consumption of large quantities of bread made from bleached flour is obviously not inconsistent with the maintenance of an ordinary state of health in most people. All will agree, however, with Mellanby's statement that carefully planned experiments with human volunteers are now required. Until such experiments have been completed the estimate that 90% of the flour consumed in this country is "agenized" cannot fail to give rise to some anxiety.

THE UNSTABLE ADOLESCENT GIRL

Criminal statistics are notoriously difficult to interpret. Whether an individual is charged or not depends as much on the social conventions of the neighbourhood, and the efficiency of the police, as on his or her behaviour. Even so, the figures given recently in the House of Lords¹ are disturbing. Whereas during the war years the overall increase in convictions has been of the order of 50%, in the case of girl offenders it has been more than fourfold. As a result the facilities for dealing with them have been overstrained and have in many cases broken down. Quite apart from the embarrassment of numbers, however, is the problem of devising scientific methods for effecting their rehabilitation. The report on the unstable adolescent girl by a joint committee set up by the Magistrates' Association and the British Medical Association, which appears at page 909 of this issue, is, therefore, timely.

The committee goes to the heart of the problem in its third paragraph: "It is important to realize that the girl's appearance in court is seldom the result of her first misdemeanour. . . . Thus the magistrate has to deal not with first offenders, but with girls whose undesirable behaviour and standards of conduct may already be well established. . . . The fundamental cause of the delinquency is usually found by the psychiatrist to be some defect of character structure." Unless these facts are kept constantly in mind, plans to deal with the problem will remain ineffective. Punishment, for instance, is of little or no avail in these cases. Had it been so, persistent misbehaviour would have been checked long ago, for few if any of these girls have escaped their share of punishment. Indeed it is this failure to react to punishment and to the disapproval of friends and relatives which constitutes a major feature of the character defect from which they suffer. To say that legal proceedings and punishment are of little avail for these cases is not to call them in question as methods of saving the ordinary citizen from speeding or shoplifting.

In fact most of us are aware that such conditions have a deterrent effect on us. That is a measure of our normality.

The failure of the persistent delinquent to respond to praise or blame is a part of her "social deficiency." The report emphasizes this: "She is lacking in feelings of love, either for her parents or anybody else; she has no sense of loyalty . . . she is incapable of friendship. . . ." This, of course, is the "lesion" from which so many delinquents suffer—a dysfunction of their capacity for loving or loyal human relationship. The origin of this dysfunction is perhaps less of a mystery to-day than formerly, when airy assumptions of constitutional factors gave a false impression of knowledge and directed attention away from the influence of environment. Psycho-analytical researches have demonstrated the developmental continuity of human relationships from the cradle to the grave. Relationships in later life are the descendants, often modified and usually camouflaged, of earlier relationships, particularly those to parents and siblings in infancy. The first of all our human relationships, that to our mothers, is in fact the foundation on which all our later relationships are based. If it is unsatisfactory, then later relationships will also be

unsatisfactory. This traditional truth has been particularly stressed by A. Freud,² Edelston,³ and others, who have drawn attention to the adverse effect of prolonged separations of mother and child in infancy and early childhood on the child's capacity for making good personal relations in later life. That such prolonged separations are specifically related to persistent delinquency has been demonstrated by Bowlby.⁴

Our greater understanding of the psychopathology of the unstable adolescent permits of a more rational approach to prevention and treatment. "Existing methods of handling these girls," the committee reports, "are often likely to exacerbate rather than improve their tendency to misconduct." Particularly to be condemned is the present tendency for girls to be sent from remand home to hostel, from hostel back to remand home, from there to a classifying school, then for a period in an approved school, and perhaps finally to Borstal. It is as though cases of advanced phthisis were, to spend months or years going from general hospitals to clinics and to convalescent homes before being sent to a properly equipped sanatorium. In the case of the unstable offender this chopping and changing is so serious because it is her incapacity to make stable and good personal relations which constitutes the heart of her illness. Frequent changes of this kind can only make matters worse.

In its recommendations the committee emphasizes that treatment and supervision of most of these girls will require to be prolonged if they are to be effective. Lay staff in charge of schools and hostels must be specially selected and trained and, it might be added, generously paid, since no work is more exacting, and a high degree of professional competence must be demanded. The nature of the training is not touched upon, but it is evident that special attention must be given to the psychology of human relations and to group techniques for dealing with individuals whose capacity for making good relationships is impaired. The work of Merino⁵ is still too little known in this country. The grave shortage of psychiatrists, both to assess personality and to undertake therapy, is stressed. This shortage will be increasingly felt as the true nature of the problem is more clearly appreciated.

Perhaps the greatest defect of the report is its relatively scant attention to preventive measures. Improvements in housing and nutrition are, of course, not unimportant, but nothing is said of other measures for promoting healthy family life. It is now well known that many homes already disrupted or in danger of disintegration can be mended by enlightened social welfare. Family clubs, such as the Peckham Health Centre, and nursery schools each have an enormous contribution to make to the promotion of good mother-child relations. Furthermore, an adequate child guidance service, with access to all children and not only to those already seriously ill, could identify in childhood many girls likely to get into difficulties in adolescence and guide them or treat them before the sorry tale of trouble has begun.

Though in some respects the committee's report fails to go sufficiently far it is none the less encouraging to find

¹ *Infants Without Families*, 1944, George Allen and Unwin.

⁴ *Who Shall Survive?*, 1934, Nervous and Mental Diseases Publishing Co., Washington, D.C.

in this document, as in most others prepared in recent years, that doctors and magistrates alike have approached their problem in a realistic and scientific spirit. Moral indignation and ignorant sentimentality have been displaced. If Samuel Butler were to chance upon this report he might perhaps wonder if, after seventy-five years, he was paying a second visit to Erewhon. But a glance at the records of the recent Titchener case would all too soon convince him that the retributive motives of the nineteenth century rather than the therapeutic outlook of Erewhon still govern much of our legal action.

DERIVATIVES OF THIOURACIL

With the demonstration of the inhibition of thyroid function by thiouracil and related compounds a new era began in the treatment of thyroid diseases. The therapeutic use of such compounds has demonstrated their efficacy in abolishing the hyperthyroid manifestations of toxic goitre, and early reports were so encouraging that their widespread and enthusiastic administration was undertaken. Dosage was often haphazard, impatience sometimes prompting the use of ever-increasing amounts, and although such measures relieved thyrotoxic patients of their symptoms it was soon apparent that the treatment was not without risk, for toxic effects were not infrequently observed and agranulocytosis often caused alarming manifestations. Such occurrences became fewer as the management of the treatment was elucidated and the quantity of the drug administered was reduced to minimal requirements, but even under the most careful conditions accidents were still apt to happen. Notwithstanding these drawbacks the treatment was obviously a great advance in therapeutics; the hyperthyroidism could be effectively controlled by maintenance therapy.

Two courses of action were now available: medical treatment only could be employed and the disease controlled apparently indefinitely, or the drug could be used to render the patient non-toxic before surgical interruption. The duration of treatment required by medical means alone was unknown, and is still debatable. In any case treatment must of necessity be protracted, and careful observation is required to avoid undesirable effects and the production of hypothyroidism. Experience has shown that although the toxic effects of these drugs are more likely to appear early in treatment, when the dosage is higher than that required for maintenance therapy, they may still occur even after months of administration. In addition the goitre itself may cause trouble by a considerable and often progressive increase in size. These hazards and the length of treatment required can be reduced to a minimum if such drugs are used as a preparatory treatment to surgical operation. Early experience showed that, although the dangers of the operation on the hyperthyroid patient were reduced by the removal of the toxic factor, the technical difficulties were often magnified, since the increased vascularity of the gland made haemostasis an almost impossible task and moreover obscured the field of operation to such an extent that it was difficult to avoid damage to surrounding structures and to assess how much gland should be removed.

It was known that previous treatment with iodine rendered the response to thiouracil less rapid. Similarly, iodine used concurrently with thiouracil diminished the response and increased the dosage required. However, it has now been found that it is possible, after obtaining the maximum desired response to thiouracil, to use iodine to produce pre-operative involution of the thyroid; and operation can then be performed before hyperthyroid manifestations recur and without the gross increase in vascularity associated with thiouracil treatment alone.

There is little doubt that the larger the dose of the compound used the greater is the liability to toxic phenomena. This has led to an investigation into related compounds to find a substance which would have greater efficacy in the reduction of thyroid secretion and less liability to produce toxic reactions. The continuation of this search is described by E. B. Astwood and W. P. Vander Laan,¹ who discuss the use of two substituted thiouracils—namely, 6-ethylthiouracil and 6-*n*-propylthiouracil. The former, which was used in only fourteen patients, showed a high order of activity, but was abandoned in favour of 6-*n*-propylthiouracil owing to difficulties in synthesis of the former and the apparent superiority of the latter, with which twenty-nine patients were treated.

It seems that this compound is as uniformly successful in controlling the hyperthyroidism rapidly and effectively as is thiouracil, but that the dosage required is much smaller. The difficulties of comparing dosage are enormous, and it is obvious that an endeavour was made to use the smallest dosage compatible with the production of an adequate therapeutic result. It is abundantly clear, however, that the dose required for both initial and maintenance therapy is many times smaller than that of thiouracil. Moreover, of these cases only one showed any evidence of toxicity, and that was a patient treated with 6-ethylthiouracil. This finding appears more significant than would perhaps be justified by the figures alone in this comparatively small series, for a number of the cases had obviously shown such marked intolerance to thiouracil itself that treatment had been abandoned. It seems therefore that 6-*n*-propylthiouracil not only shows greater activity in reducing thyroid secretion than its parent compound but has, as the authors suggest, a greater specificity in its action and in consequence is freer from side-effects. There is little doubt that it is a considerable advance on thiouracil, but its discovery must not be regarded as ending the search. One patient in this series developed progressive enlargement of the goitre in spite of very small doses. It is hoped that further work will be done to find a better compound

TREATMENT OF AGRANULOCYTOSIS

In this issue of the *Journal* (p. 897) Librach and Cronin report an example of an unusual type of agranulocytosis in which recovery followed pentose nucleotide given by continuous intramuscular drip. Their discussion of the case closes on a note of scepticism. They conclude that recovery was spontaneous and not determined by their novel method of administering this drug. This comment would be endorsed by others who have experience of treating

feature of the condition. Nisbet describes the following three types of reaction, and though all stages may be seen in the same patient the lichenoid and generalized eruptions commonly follow the patchy eczematoid. (1) The patchy eczematoid type accounts for 30–40% of cases; the hands and feet, groins, eyes, and ears are the sites of election. (2) The hypertrophic lichenoid type may arise as such primarily but usually follows the former type. Spread is rapid, and the appearances resemble a very severe and unusually extensive chronic hypertrophic lichen planus. Mucous membranes are involved, as are the scalp and the face. The latter is rarely attacked in true lichen planus. A peculiar bluish-grey pigmentation occurs. The typical polygonal papules with flat, shining surface are absent, and the glans penis is not affected. (3) The generalized exfoliative type usually follows upon the eczematoid or lichenoid. If it is a primary occurrence it may be acute and oedematous and cause pyrexia.

The patients are ill and unfit for duty, are in hospital for an average period of three and a half months after being evacuated from the Tropics, and may not recover for six to twelve months. Pigmentation may be very persistent and in some cases a fine reticular atrophy is seen. Hair and nails were often shed, but they grew again in all cases observed. No drug therapy proved of value except penicillin for the secondary sepsis that was a frequent complication. Nisbet thought that light aggravated his cases, but Schmitt and his fellow-workers did not find this. They stressed the affection of mucous membranes in one-third of the cases, the presence of glandular enlargement, and occasional pyrexia. Their paper gives in more detail several case histories and is well illustrated. They discuss the differential diagnosis from eczema, contact dermatitis, urticaria, lichen planus, heat rash, and fungous infections.

The incidence of this adverse response to mepacrine was not sufficiently high to justify withdrawal of the drug from general use, but those subject to the disturbance could not subsequently take the drug without relapse of the dermatosis. They had therefore to be withdrawn from those areas where prophylactic measures against malaria were necessary.

VITAMINS IN HUMAN MILK

Carefully planned and co-ordinated investigations recently reported by Macy and others¹ provide further information on the vitamin contents of human milk, and an accurate assessment has been made of the substantial demands for these nutrients made by the infants. The general plan of the experiments was to estimate the vitamins by chemical or microbiological methods in specimens of colostrum and of mature milk taken from large numbers of mothers at successive intervals after parturition. It was fully realized by Davies and colleagues² that the composition of milk varies greatly according to whether it is collected in the early or late stages of any particular withdrawal, and precautions were taken to avoid undue errors from this source. Usually the milk from mothers on a carefully chosen institutional diet was compared with that of mothers who had chosen their own diet, but the differences found, even if in some cases statistically significant, were relatively small. It is perhaps remarkable that even the approved diet failed to reach the standards originally recommended by the U.S.A. National Research Council for ascorbic acid, thiamin, and nicotinic acid. Yet the diet included liberal quantities of chicken, eggs, liver, spinach, carrots, apricots, butter, cream,

and milk: the authors hint that for normal adults the official standards may have been unduly high.

The different concentrations of vitamins in colostrum and mature milk was one of the points studied. Previous knowledge has been confirmed, and valuable new facts have been collected. Thus, as compared with mature milk, colostrum contains ten times more carotene, twice as much vitamin A, and half as much again of ascorbic acid and nicotinic acid. On the other hand milk is about five times richer in pantothenic acid than is colostrum; the concentration of biotin is doubled as the milk matures, and the content of thiamin and riboflavin increases greatly. A difference in behaviour between fat-soluble and water-soluble vitamins might perhaps have been expected, but the observed divergences between the various water-soluble vitamins present an interesting problem to the biochemist.

Equally interesting, and possibly of more practical importance, are the differences shown by Lawrence and his colleagues³ in the vitamin contents of mature human milk and mature cows' milk. The data for human milk were mostly taken from Macy's investigations,¹ with the women choosing their own diets. Human milk is much richer than cows' milk in vitamin A, ascorbic acid, nicotinic acid, inositol, and folic acid, and much poorer in thiamin, riboflavin, and biotin. The differences between human milk and cows' milk are even more numerous than had been suspected and provide a further pointer to the superiority of human milk to cows' milk for infant feeding. But lactation makes severe demands on the mother's vitamins. If 900 ml. per day is taken as a typical output during the middle stages of lactation, the mother loses on an average 585 µg., or about 2,000 I.U., of vitamin A, and 45 mg. of ascorbic acid daily. Experiments by the Medical Research Council⁴ have shown that 1,250 I.U. of vitamin A daily are enough to cure experimental deficiency in adult humans, while a daily intake of 45 mg. of ascorbic acid would be considered by many to be an adequate safeguard against scurvy. The drain by lactation on the mother's reserves of these two vitamins is therefore considerable when compared with the normal daily requirements, and the National Research Council of the U.S.A. has ample justification in setting high standards of intake for lactating women.

R.M.B.F. CHRISTMAS APPEAL

Sir Arnold Lawson, long an active worker for the Royal Medical Benevolent Fund, is now its President in succession to the late Sir Thomas Barlow, and he takes the same personal interest in the Annual Christmas Appeal on behalf of the poor beneficiaries of the Fund. Last year he asked for £2,000, and his appeal brought in £2,127, which provided £4 for each beneficiary. These gifts were very welcome as a token of goodwill from members of the medical profession and as a means of buying a few extra comforts for Christmas. A short time ago Sir Arnold Lawson wrote to ask our readers for a similar sum this year, and his letter appeared in the *Journal* of Oct. 19 (p. 588). Life is difficult for everybody these days, but especially for those "very poor brethren" whom the R.M.B.F. takes under its wing. We hope that all who can help and have not yet responded to the appeal will do so at once. Donations marked "Christmas Gifts" should be sent to the Secretary, Royal Medical Benevolent Fund, 1, Balliol House, Manor Fields, Putney, London, S.W.15.

Viscount Addison, M.D., F.R.C.S., Secretary of State for Dominion Affairs, has received the signal honour of appointment by the King to the Order of the Garter.

THE UNSTABLE ADOLESCENT GIRL

The following appendix to the Report of the Committee on Psychiatry and the Law has been approved by the British Medical Association and the Magistrates' Association.

I. The Problem

1. The girl with whom the committee is concerned in this investigation is usually between 13 and 17 years of age and she comes before the court on a charge of stealing or because she is out of control, or is in moral danger or in need of care and protection. Superficially she is a "good-time girl," living only for her own personal enjoyment, morally and emotionally unstable, perhaps guilty of sexual misbehaviour, and unamenable to discipline and control. Her appearance in court is followed by an investigation by the probation officer, a stay in a remand home, then perhaps a period in a hostel; and, if that is not successful, she may finally be sent to an approved school, which to her means a sentence of imprisonment.

2. The existence of this type of girl in the community is a serious social problem which at present is being far from satisfactorily handled. The causes and the nature of the problem are not always clearly understood or appreciated by those concerned with such girls. The facilities for dealing with it are inadequate, and those that exist are not always fully utilized. The general attitude towards the girl is often mistaken; little attempt is made to prevent her undesirable behaviour, and the decision of the court or other authority often serves only to increase her difficulty.

3. It is important to recognize that the girl's appearance in court is seldom the result of her first misdemeanour. Investigation usually shows that the girl charged with theft has been stealing for a considerable period and has either succeeded in remaining undetected or her victims have taken no action against her. Similarly in girls charged with civil offences there will usually be found a long-standing history of a tendency to sexual deviation and refusal to accept parental control. Thus, the magistrate has to deal not with first offenders but with girls whose undesirable behaviour and standards of conduct may already be well established.

4. Investigation will usually reveal that the girl's behaviour is the result of interaction between temperament and environment, but always at the root there is some defect of character-structure that is the real cause of her difficulty. It is not necessarily a defect of intellect but rather a degree of social insufficiency. The concept of social deficiency is not yet generally understood, and work on the measurement of social defect has not yet reached the stage for practical adoption, but it appears to the committee that consideration of the problem of the unstable adolescent girl and of the means of dealing with it must take full account of this character defect and of its consequences to the individual and to the community.

The Probation Officer's Findings

5. The emotionally unstable girl appears in all walks of life, but investigations by probation officers and psychiatrists reveal all too often an unfavourable environmental history. Frequently the normal home life is found to have been broken by the death or absence of one or both parents, or else there is such gross overcrowding or such disharmony among the members of the family that ordinary healthy adolescence is wellnigh impossible. The absence of parental love and understanding and control and the lack of stability and security in the home are a serious loss to a girl in her teens, and she may try to find compensations outside the home. She picks up casually a superficial knowledge of the "facts of life," makes undesirable acquaintances, and frequently comes into contact with the law.

6. Again, it may be found that the girl is unhappy in her work. She has left school at the age of 14 and immediately begins work in the first job that offers, whether or not it is suited to her ability or inclinations. Her outlook on life is changed almost overnight from that of a dependent child to that of a grown-up who, as long as she makes her weekly contribution to the family exchequer, may be independent of parental control, may seek her own recreation and friends of

either sex, and may spend whatever money she keeps for herself on personal adornment and pleasure. She is not interested in her work, she has no security in her firm, and she may drift from one job to another without striking root.

7. The war must take its share of responsibility. Irregular schooling, evacuation, sleeping in shelters, and bad housing may have accentuated any tendency to moral or emotional instability and may often have provided temptation. But there has also been in recent years, apart from the effects of the war, a general slackening of adult moral standards; the general trend of legislation and propaganda has weakened the sense of parental responsibility; the influence of religious and spiritual values has diminished; and family life has for many people lost much of its attraction and satisfaction. Against such a background it is small wonder that a proportion of girls go astray.

8. In some cases the girl has been brought up in an institution and has never known home life. For the first time she comes into contact with girls who have real homes and she feels her own inferiority in this respect. Having no sense of responsibility towards anyone, she is self-centred and seeks only her own gratification; and, being without knowledge of the value of the money she earns, or of the standards of behaviour in life outside the institution, she frequently finds herself in trouble.

The Psychiatrist's Findings

9. The circumstances mentioned above are those that probation officers find in the environment of girls appearing before the courts, but the psychiatrist can explore more deeply into the cause of the girl's trouble. A bad environment does not necessarily produce delinquency, and, indeed, it is a matter for wonder that large numbers of girls in atrocious situations rise above them and keep straight. The fundamental cause of the delinquency is usually found by the psychiatrist to be some defect of character-structure, not always amounting to a mental defect. It is often found that the undesirable behaviour dates from a period closely associated with the onset of puberty, occasionally starting some months or even a year before its onset.

10. In a minority of cases a degree of mental deficiency will be found. The I.Q. of this group is frequently below 70; if it is above 70 they are apt not to be regarded as mental deficiency cases because of a misinterpretation of the Mental Deficiency Acts. The point which it is necessary to bring out is that moral or social deficiency is not necessarily measured in terms of low I.Q. Certification under the Mental Deficiency Acts does not therefore necessarily depend on the I.Q., and these Acts should not be interpreted in this way.

11. In order to prevent any misunderstanding it may perhaps be pointed out that the term "mental deficiency" in the Education Act, 1921, has disappeared from the new Education Act, 1944, and that certification as mentally defective under the former Act has been abolished. Now, under the new Act the degree of disability of mind of a child is based entirely on the degree of educability, and it is only when the disability of mind is of such a nature and extent as to make the child incapable of receiving education at school that the child is reported to the Mental Deficiency Acts Authority as a subject to be dealt with by them. This procedure includes the child who, besides being educationally subnormal, should not be educated with other children either in her own interests or in theirs. It will thus be seen that certification as a mental defective can only be carried out now under the Mental Deficiency Acts.

12. In the case of a girl with an I.Q. of 60 or under the physical development is often retarded, and she appears from the physical point of view to be younger than her age and has a definitely childish manner. This type of mental defective is often facile, friendly, and apparently co-operative, and may even appear to be superficially bright. She frequently chatters away, but soon reveals the fact that she is lacking in self-criticism and that her powers of reasoning and judgment are poor. She does not really appreciate the social implications of her behaviour or the personal consequences.

13. On the emotional side there is a notable deficiency, that is to say, she is lacking in feelings of love either for her parents or anybody else; she has no sense of loyalty either to her home, her school, or employers; she has no sense of duty or

obligation to the community; she is incapable of friendship, although she not infrequently goes about with a girl who is somewhat similar to herself in tastes and temperament but whom she is quite ready to throw over or to blame if her own interests demand it. She is lacking in any kind of ambition; she seldom shows a preference for any particular type of occupation, and is lazy and lacking in drive and initiative. She is impatient of any kind of discipline or control and usually becomes sulky or hostile if she is criticized or thwarted.

14. If she steals she does it so stupidly and childishly that she is nearly always found out. She invariably tries to lie herself out of the difficulty but does it so badly that she is easily detected. If she steals she usually takes money, clothes, or jewellery for her own personal use. Her sexual adventures are also of a very elemental and primitive type. She is completely indiscriminating and will go with any man who makes overtures to her regardless of whether he is personally attractive. Girls of this type seem to be quite unable to visualize the future or to adopt a long-term policy; the gratification of the moment is the limit of their mental horizon.

The Home Life

15. Most of these girls of lowered mentality come from unsatisfactory homes. In many cases the mother is herself a mental defective or mentally subnormal, and quite often the father is of a similar type. The moral standards are frequently low and there is a complete lack of sense of social responsibility or of any spiritual values, so that the child has lacked any influence that might help to modify her own unfavourable innate tendencies. Quite often the parents quarrel or are separated or drink or are work-shy or frankly dishonest, and the girl has had no love from them. She has been ill-nourished and ill-clad and regards her home and her parents with hostility and often with fear. On the other hand in a few cases the home is of quite a good type and the parents and other children satisfactory, the patient being the one black sheep.

16. But mental defectives in terms of intellectual inferiority are in a minority. Most of the unstable girls who come before the courts have an intellectual capacity between 70 and 90, the commonest range being between 74 and 88, but an I.Q. of 100 may be encountered. Unlike the girls with an intelligence quotient of 60 and under, these girls often show precocious physical development, especially in the breasts and hips, and it is not uncommon for a girl of 14 or 15 to appear to be 17 or 18 in her general development. Emotionally they closely resemble those of a lower intelligence, but their actions are much more premeditated and organized, and they show more discrimination in the type of men they go with, deliberately choosing those who have money and, if they can get them, men with some physical attraction. They are cleverer at covering up their traces, and their lies are much more circumstantial and specious. They spend a great deal of time on making up their faces and adorning themselves, though they often do not trouble to wash and are sluttish about their undergarments. Their favourite reading matter consists of the weekly journals dealing with the love life of film stars, and they live in a fantasy world of erotic glamour. Frequently they are a good deal more intelligent and sophisticated than their parents, whom they outwit and despise. They sometimes appear docile and submissive to authority so long as they are definitely in its power, but their promises are like piecrust, and they are, as a rule, only waiting for a chance to get free in order to resume their former way of life.

17. These girls very often come from a broken home, but on the whole the parents tend to be of a higher mental level than those of the defective girls, though their moral standards are frequently very low and the home background is lacking in comfort and affection. Another type of home which may be productive of cases of this kind is that which is dominated by a very narrow and rigid set of religious values. In a certain number of cases, however, the home is quite satisfactory and the parents are decent intelligent people who have done their best to bring up their family to be honest and responsible citizens.

18. It is usually found that there has been no proper and adequate sex education.

19. There is a special type of girl which should be recognized. She is over-sexual in her behaviour and easily picked

up, but is essentially over-ingenuous, over-trusting, and over-credulous where admiration from men and what she thinks is romance are concerned. She easily imagines herself in love, but in fact has a less than average capacity for the non-sexual expression of affection and for any permanent love. Her behaviour, apart from her sexual behaviour, is not usually either asocial or antisocial—at any rate to begin with—consequently she is not a moral defective in terms of the Mental Deficiency Acts. Her intelligence level is not characteristic and may be high or low, though many seen in court are of low intelligence. She shows in many ways a general emotional immaturity, but this is often masked by the pseudo-sophisticated air lent by her sexuality.

This type of girl may easily acquire venereal disease or produce illegitimate children and may develop into a true nymphomaniac—i.e., a person who feels (and usually obeys) a very strong inner urge to behave sexually with any man who attracts her.

Such cases usually come under notice in adolescence but may not be discovered until they are in the early twenties. They are primarily a medical problem, and, if not of too low intelligence or too antisocial in other ways, can be helped by psychological treatment, which must be prolonged and often begin under residential supervision, which may suffice in itself. Every possible effort should be made to persuade such girls to co-operate voluntarily and undergo residential treatment. Punishment alone is unlikely to have a favourable effect on them.

II. Present Methods of Dealing with the Problem

20. Under the Children and Young Persons Act only girls under the age of 17 can be brought before the court as in need of care or protection, although the year or two after that age often prove the most difficult and dangerous for the emotionally unstable girl. The facilities available to the juvenile courts in dealing with her are entirely inadequate, especially in regard to approved homes, hostels, and lodgings. A member of the committee has described in the following words the probable experiences of the girl after her appearance in court:

"When she appears in court—either as being in moral danger or for petty theft—she may be put under the supervision of a probation officer and will really intend to settle down at home if she is given a chance by both parent and court to do so. As she has never been taught that she has any obligations in return for her 'rights,' she will resent any attempt to control her undisciplined way of life and will probably completely disappear for several days after the first row at home. When she is found again she has nearly always had sex relations with one or two men, sometimes more.

"Then will follow all the emotionally upsetting series of events—the full statement of her story to the women police, the stay in the remand home exchanging stories with her companions there, perhaps the interview with the psychiatrist—too superficial to help either girl or magistrate—the medical tests, and the appearance again in court with the gnawing anxiety as to what 'They' will do with her. This time perhaps she is given a chance in a hostel: owing to the shortage of the places it will have to be chosen by a harassed probation officer on account of a vacancy more than because of its suitability. The probation officer will assure her she will try and find somewhere else if she is really unhappy and will watch anxiously to see if she settles down. As before a short cut to everything will be wanted; and as these hostels so often have not the homely atmosphere and friendly welcome both girl and probation officer are trying to find, it is often only a question of a few weeks before she is off again. 'Too much religion,' 'Too many rules,' 'Didn't like the type of girl,' are some of the reasons afterwards given when she again appears in court. This time it will almost certainly be an 'approved school,' and a sobbing or defiant girl is led out of court feeling the worst that could happen has fallen on her. She will not go direct to the school but back to the remand home to await a vacancy in a school chosen by the Home Office. If the Home Office, on reading her reports, consider she is likely to respond to 'being classified,' she will be sent—sometimes after a wait of 4 or 5 months in a remand home—to one of the two classifying centres for girls. Here she will undergo tests of every kind, get perhaps a little more physical exercise than in the remand home, have to make new friends, get used to a new staff; and after 10 to 12 weeks of this, off she goes at last to her school."

21. Such an experience is obviously unsettling to a girl in her teens already emotionally unstable, and when her period of detention is over she returns to exactly the same environment

and influences that were probably at least partly responsible for her misconduct.

22. Not only are facilities for dealing with these girls inadequate, but those that are available are often of the wrong kind. It is wrong to treat as guilty of an offence a girl who needs and cannot find care and protection. An emotionally unstable girl requires a special type of remand home. Even when a period in an institution is the right course for the particular girl, care is not always taken to ensure that the right type of institution is chosen or that she is not placed indiscriminately among other more normal types of resident. Such lack of care is often responsible for unsatisfactory results, for it means that the girl's special condition and needs do not receive proper recognition and treatment. In short, existing methods of handling these girls are often likely to exacerbate rather than improve their tendency to misconduct.

23. The facilities that are available are not always used to the fullest extent. Medical officers of health, for example, are frequently unwilling to certify girls as mentally deficient even when this course would be the most appropriate way of dealing with them. There is also the complaint that there is insufficient co-operation between statutory and voluntary bodies.

24. Many girls could be helped to resolve their own difficulties of adjustment by psychiatric guidance, but the facilities available at out-patient departments or at psychiatric clinics are entirely inadequate and the number of psychiatrists available is far too few.

III. The Remedy

25. In order to deal effectively with these girls there must be, first, a fuller recognition of the general nature and causes of their misbehaviour and of the objects of treatment; secondly, there must be more facilities and skilled staff for the investigation and treatment of individual cases; and, thirdly, more clinics and institutions for the purpose of treatment and control must be provided.

26. Obviously, under the first heading will come the improvement of environment. Overcrowding, bad housing, and malnutrition must be eliminated. The raising of the school age, with the consequent longer period of school discipline, may help, and so should the effective application of the Ministry of Labour's schemes for guiding young people into suitable employment. In the latter schemes the assistance of a psychiatrist or a child guidance clinic may be helpful in finding the right type of employment for girls who appear to be emotionally unstable. Often all that such a girl needs is some activity that will bring variety, colour, and interest into her drab life, and this is just what the unimaginative decisions of officials fail to realize. There are many activities and outlets, whether as paid employment or as leisure time hobbies, that could be found or provided to help these girls to readjust themselves.

27. There are other social means of preventing the development of sexual and social misconduct, such as the strengthening of the ties between home and school, and the encouragement of the work of voluntary societies, and youth organizations such as clubs.

28. There must be more facilities and staff for the investigation of individual cases, apart from inquiries into environment. A full and skilled investigation requires the services of a psychiatrist. The present provision of psychiatrists is quite inadequate for full investigation of all the cases needing inquiry. Psychiatric investigation should take into account the girl's personality, temperament, intellectual capacity, sexual propensity, and the interaction between character and environment. Emphasis needs to be placed on the girl's social capacity rather than on her intelligence quotient. For this purpose the kind of research at present being conducted in Bristol and elsewhere in the assessment and classification of social deficiency should receive every encouragement.

29. Long-term treatment or at least prolonged supervision will be required by most of the girls, and it must be recognized that the efficient handling of a case involves a deliberate search for the best method of treatment for the particular girl concerned. Many more psychiatrists are required for investigations at child guidance clinics, observation centres, and out-patient departments, and for visiting the girls in their schools and institutions.

30. The latter necessity raises an important question of organization, for there will not for a long time be sufficient psychiatrists to provide a psychiatric service for all the schools and institutions to which these girls may be sent. It is suggested, therefore, that in the meantime particular approved schools should be selected for the purpose of receiving emotionally unstable girls in urgent need of treatment, and arrangements should be made for these schools to be visited regularly by psychiatrists who will supervise the progress of the individual girls and also advise the lay staff on matters affecting the treatment and control of the patients. A psychiatrist undertaking this work should hold a part-time appointment only, for it is undesirable from the point of view of his own skill that he should devote himself to this single aspect of psychiatry and from the point of view of the girl that he should be identified with the official control of her life.

31. The psychiatric treatment of emotionally unstable girls is extremely important, for the majority respond to the individual approach of a doctor who understands and sympathizes with their personal difficulties and emotional conflicts. The psychiatrist has the advantage of being an understanding outside person to whom the patient can talk freely with the knowledge that her confidences will be respected and that the doctor is there to consider her personal interests. No one else in her environment can qualify for this role, and yet it is just that relationship that the emotionally unstable adolescent girl needs. The psychiatrist can help her to build up a series of values which are socially acceptable and also acceptable to the girl herself. The chief difficulty he has to overcome is, of course, that the life which she has chosen, with its self-indulgence and emotional gratification, is far more attractive to her than anything he can offer.

32. The lay staff in charge of schools, hostels, or colonies to which this type of girl may be sent should be specially selected and trained. It cannot be expected that such girls will respond to treatment unless the persons in charge of them possess qualities of understanding, sympathy, and patience and have a real love for the girls in their care. People with these qualities are unfortunately few and far between, and at the present time methods and standards of training and preparation for the holding of such posts are entirely inadequate. Persons with a natural flair for this kind of work are needed, but they must also have adequate training, for, from the psychological point of view, it is often the well-meaning but ignorant people who do most harm.

33. Greater facilities are required for dealing with such girls. For girls from school-leaving age there should be greater provision of homes, hostels, and suitable lodgings under supervision. Certification under the Mental Deficiency Acts may be possible and the best course for certain types. Others are often better under the influence of an approved school or an appropriate hostel. For those of compulsory school age the provision of boarding special schools under the Education Act of 1944 is a solution.

34. Facilities required for the treatment of emotionally unstable girls are of several types. The average remand home is quite unable to cope with them in the early days of their control. Observation centres are badly needed for their reception while investigations are being made, by both the psychiatrist and the social worker. The necessity for long-term treatment for the emotionally unstable girl must be recognized. For the most part they are not likely to respond to a short course of discipline or training, and in most cases it is quite hopeless to try to treat them in a psychiatric out-patient department or child guidance clinic. They need a prolonged stay of perhaps two or three years in a suitable school or hostel or institution run on the colony system, where they would receive training and discipline combined with psychiatric treatment. In many ways girls of higher intelligence are more dangerous to the community than girls of a lower intellectual capacity. If they marry and have children they usually make bad wives and bad parents; and, because of their emotional immaturity and instability, they do not develop until very late, if at all, the capacity for maternal love or a sense of parental responsibility. At the present time it is almost impossible to keep girls under control long enough for any constructive treatment to be effective.

35. A most important need is for proper and adequate sex education and the training of adolescents in handling their emotional problems. This, as a matter of principle, should come from the parents, but if they are not capable of dealing satisfactorily with this essential aspect of the child's education it should be the responsibility of the education authority.

IV. Aftercare

36. The period after discharge from an institution or approved school is extremely critical. There are bound to be difficulties of adjustment to normal life. It is essential that these girls should be given every possible help and protection at this stage if they are to avoid a relapse. Facilities for adequate aftercare must therefore be provided. Magistrates should have the power to require that delinquents should place themselves under the care of specially appointed social welfare officers for a period of at least 12 months after discharge.

37. It is felt that the aftercare of girls should start almost as soon as they enter the approved school or institution, and that the aftercare officer should, all the time that the girl is away, be in close contact with the home, using her influence to reform the home while the girl is being reformed. Reconciliations between parents and training the mother in a friendly way can be undertaken during this period. Thus, when the girl leaves, the aftercare officer should already be the friend of both the girl herself and her relatives at home.

38. There is urgent need that more hostels under a hostel warden should be provided in conjunction with approved schools. Many girls would benefit by a short transition period in such a hostel before returning to their own homes. This would enable the girl to prove that she can work steadily and make a right use of her freedom under supervision before making her new start in the wider world.

V. The Limitations of Treatment

39. When all has been done that it is possible to do there will inevitably remain some girls for whom all help and treatment seem useless. In them the defect of character or of social capacity is so fundamental as to hold out little hope of transforming them into satisfactory members of society. They have neither the capacity nor the will to co-operate in anything that is done for them, and the moment they are liberated from control they will go back to their former bad ways.

40. It is important that this limitation of treatment should be recognized, for it is the failure of psychiatry to effect cures in these all but impossible cases that has tended to bring discredit upon psychiatrists and those who believe that the right method of treating these offenders is by methods aiming at reclamation rather than retribution. But the committee believes that when there are sufficient institutions, staffed by properly trained and experienced persons, and when they have had an opportunity to show what they can do after a sufficiently long period of years, it will be seen that the psychiatric approach to the problem is the right one and is successful in the great majority of cases, and that it is in the best interests of the girls themselves and of the community.

FRANCIS AMORY SEPTENNIAL PRIZE

In compliance with the terms of a gift under the will of the late Francis Amory of Beverly, Massachusetts, the American Academy of Arts and Sciences offers a substantial prize for outstanding work addressed to the alleviation or cure of diseases affecting human reproductive organs. The gift provides a fund the income of which may be awarded at seven-year intervals "as a prize and gold medal, or other token of honour or merit," to any individual or individuals for work of "extraordinary or exceptional merit" in this field. In case there has appeared work of a quality to warrant it the next award will be made in 1947. Awards will be made for what in the judgment of the committee on the Amory Fund appears to be the most outstanding contribution or contributions in the field as outlined and as based on published work and recognized accomplishment for the current seven-year period.

No formal applications and no essays or treatises from individuals are solicited, but suggestions will be welcome from any appropriate source that will be of aid to the committee in making a wise selection.

Recommendations may be addressed to the secretary, Amory Fund Committee, American Academy of Arts and Sciences, 28 Newbury Street, Boston, Massachusetts.

STORIES OF ENDOCRINE RESEARCH

THE ADDISON LECTURE

The first Addison Lecture was delivered at Guy's Hospital on Monday, Dec. 2, by Prof. E. C. Dodds, with Lord Cunliffe, the treasurer of the hospital, in the chair. The objects of the lecture, which has been established through a gift to the medical school of an old Guy's student, Dr. Harry Spon, are to commemorate the fundamental contributions to endocrinology made by Thomas Addison at Guy's in the middle of the last century; to indicate the importance with which this rapidly developing branch of medicine is regarded; to stimulate the interest of the student by introducing to him men with whose names and work he is already familiar; and to pay a compliment to certain distinguished endocrinologists by inviting them to deliver the lecture.

Prof. Dodds chose "Stories of Endocrine Research" as his title. Taking endocrinology as an example he reviewed various techniques or "disciplines" of research. He dealt first with the "Addisonian" or "Guy's" method. By careful clinical observation correlated with shrewd analysis of post-mortem findings it was possible for Thomas Addison to describe in 1855 the disease which was subsequently called after him, and to indicate that it was due to destruction of the suprarenal glands. By similar methods Sir William Gull in 1873 was able to describe the syndrome of myxoedema and associate it with the cretinism of infancy due to thyroid failure. These two great Guy's men were rather similar in character, both being forceful men of great personality. In clinical matters they were profoundly wise and almost tediously thorough. Addison, for instance, would remain at the bedside, doggedly determined to trace out the disease to its very source, for a period which constantly wearied the class and his attendant friends. Both men were greatly helped by Benjamin Harrison, the treasurer of Guy's at that time.

Confirmation and Synthesis

The fundamental observations of Addison were confirmed by Brown-Séquard on animals from which the suprarenals were removed. In 1931 Swingle and Pfiffner were able to maintain life in adrenalectomized animals by means of a crude cortical extract, and to-day it was possible to restore to health patients suffering from Addison's disease by using the synthetic hormone desoxycorticosterone.

Gull's observations were confirmed by Ord, who gave the cretinoid condition the name of "myxoedema," and it was reported by Kocher that this state was liable to supervene after complete thyroidectomy. In 1891 George Murray treated a case of myxoedema with an extract of sheep's thyroid; in 1915 thyroxine was isolated in crystalline form by Kendall, and it was synthesized in 1927 by Harington and Barger.

Often the method of clinical observation hung fire, and this was shown in the case of Thomas Willis, who in 1681 described the sweet taste of the urine in diabetes. Little progress was made with this subject for two centuries, until von Mering and Minkowski made the chance discovery that removal of the pancreas produced diabetes. Six more years elapsed before in 1895 it was observed that ligation of the pancreatic duct produced degeneration of the gland but not diabetes. It was this observation that prompted Banting in 1920 to attempt to make an extract of the islet tissue after ligaturing the duct in order to destroy the enzymes which might be antagonistic to the islet hormone. This planned experiment by Banting and Best led to the discovery of insulin.

Incidental Discovery

In sharp contrast was the type of research in which a man set out to discover one thing and found out something else. The isolation of vitamin C by Szent-Györgyi was an example. For he set out to study biological oxidation, which he considered to be a function of the adrenal cortex. Having isolated from it the powerful reducing substance "hexuronic acid," he later showed that it had the antiscorbutic properties of citrous fruit extracts and was, in fact, ascorbic acid.

As his last example of how scientific discoveries were made Prof. Dodds chose the story of the sex hormones. With the effects of castration known for years, and the description by

Allen and Doisy of a simple method of assaying ovarian extract by the vaginal smear technique, the stage was set for the isolation of the oestrogenic hormone. At about this time the fundamental facts of sterol chemistry were being elucidated, and the structure of the cyclo-penteno-phenanthrene ring system was finally elucidated by Rosenheim and King. In 1927 Aschheim and Zondek discovered the urine in pregnancy to be a concentrated source of oestrogenic substances, and from this fluid, with the essential information provided by Windaus and Wieland and by Rosenheim and King, five oestrogenic compounds were isolated almost simultaneously by Butenandt, Doisy, Marrian, and Girard in 1932. From the fact that at least five separate oestrogens had been isolated from this sterol structure it occurred to Dodds to see how specific the molecular structure was for oestrogenic activity. After a while it was found that the phenanthrene structure was not essential, and anol, a simple benzene compound, was found to have an oestrogenic potency which appeared to be high. On repetition of the work, however, it was realized that the activity of the original batch of anol was due to a contaminant. Pursuing the work in collaboration with Sir Robert Robinson, the compound stilboestrol was finally made and found to have a very high degree of oestrogenic potency.

In concluding his lecture Prof. Dodds emphasized that research was not only for heaven-sent geniuses—an impression which was largely due to the invariable scientific practice of writing the paper backwards, which gave the research an appearance of being a carefully thought out, orderly procedure. In fact, however, the research was done by a series of blundering steps in which the worker was rather like someone in a dark room scrambling for the switch and tripping over the furniture. When he had once found the switch and turned on the light he was able to arrange the furniture in an orderly manner.

HEALTH SERVICES IN PALESTINE

Prof. Samson Wright, who visited Palestine in the earlier part of the present year, gave a lecture at Palestine House, London, on Nov. 28 on the health services in a country which he described as straddling between the patriarchal period and the twentieth century. During the twenty-five years of the mandate Palestine has become Westernized in places and has moved forward everywhere, but it still comprises an extraordinary mixture of ancient and modern. Its population is under two millions, including 600,000 Jews and twice as many Arabs. Each of these races has increased roughly by half during the last quarter of a century, but the Arab increase is largely due to high natural fertility and the Jewish increase largely to immigration. The Palestinian budget is over 20 million pounds, but the allocation of the Palestine Government for health services is only some £600,000, with an estimate of £800,000 for the coming year. These figures are much higher than in the earlier years of the mandate, and have risen steeply during the war, but they are still comparatively small. The Government hospital service, according to Prof. Wright, has in the main been directed to the service of the Arab population. In the Government hospital in Jerusalem the overwhelming majority of the patients and a large proportion of the staff are Arab. The Jews have more or less developed their own services, and are spending on them for the current year over two million pounds, less than £200,000 of which is contributed from outside Palestine.

Prof. Wright gave some vital statistics. In 1925 the Jewish death rate was 14 per thousand; it had steadily fallen and was now 7 per thousand. The Arab (Moslem) death rate had fallen during the same period from 29 to 17. Jewish infant mortality had fallen since 1925 from 132 per thousand to 56, and Moslem from about 200 to 100. Intestinal infections have decreased, and there has been a great fall in the incidence of trachoma, which immediately after the war of 1914-18 was some 30%, and now is a small fraction of 1%.

Prof. Wright described the curious form of social health insurance obtaining in Palestine. It is run by the National Federation of Labour, a Jewish trade union organization instituted at the beginning of the mandate. In 1944 the membership was 135,000, and as the arrangements include the breadwinner's family it follows that a substantial proportion of Jewish people

are provided for in this way. Last year £50,000 was paid by the Government to the sick fund of this organization, which has built its own clinics and dispensaries and employs its own doctors. The doctors in this organization are dissatisfied with their salaries. A practitioner of the consultant class receives only about £700 a year, which, taking into account certain deductions that are made and the high cost of living in Palestine, is equivalent to no more than £500 in this country. But Palestine has a surplus of doctors, and if a man resigns there are two ready to step into his shoes. It is said to be impossible to get the Arabs to agree to tax themselves for health services. The most desirable thing for the health of Palestine would be to obtain Arab contributions to health services proportional to those which the Jews are making.

Prof. Wright painted a rather sombre picture of some of the general health and social conditions in Palestine. Overcrowding is rife. In this country one family in a room is something of a scandal; in Palestine it is regarded as a lucky family. There is a good deal of malnutrition, particularly in the towns. Hospital accommodation is very inadequate for certain classes of patients, for example the tuberculous. The most crying need is for accommodation for mental cases. Unless the mentally disordered person is likely to murder his neighbour he is allowed to remain in the family and the community. Prof. Wright had also been distressed to find, even in a small city like Jerusalem (200,000 population), how little contact there was between the British authorities running their hospital and the Jewish authorities running theirs only ten minutes' ride away.

"REMPLOY"

The Disabled Persons' Employment Corporation, Ltd., a non-profit-making organization, was set up by Mr. Ernest Bevin when Minister of Labour and National Service to provide employment in factories (and in homes for the home-bound) for all classes of registered disabled persons who are so severely handicapped as to be unable to obtain employment otherwise. It is establishing factories which are known as "Remploy" factories. The first was opened at Bridgend, Glamorgan, on Nov. 27, 1946, and the second at Salford on Dec. 9. The Corporation anticipates that eight factories will be operating by next April and a further forty in the ensuing twelve months. It is hoped to include the following northern towns: Oldham, Leeds, Sheffield, Wakefield, Bolton, Preston, and perhaps Burnley, Bradford, and Wallasey. Wages are paid during instruction as well as for subsequent employment on productive work—the full trade rate being applicable to competent persons. The factories' products bear the name "Remploy."

Special factories for the tuberculous will be established where needed, and it is hoped that one for post-sanatorium cases will be functioning in twelve to eighteen months' time. Special provision will be made for epileptics, but at the moment the problem is complicated by the reluctance of some of those so disabled to register themselves. The factories will supply raw materials, tools, and instruction to home workers, so that in time a chain of "cottage industries" may be built up.

CARE OF THE ELDERLY

A conference on the care of old people arranged by the National Old People's Welfare Committee, in association with the National Council of Social Service, was held on Nov. 29 and 30 and attended by about 420 delegates.

The Rt. Hon. James Griffiths, Minister of National Insurance, said that increased old age pensions had been paid from the first week in October, when there were 4,100,000 pensioners. About 1,900,000 old folk who were previously receiving pensions at the basic rate of ten shillings or twenty shillings (married couples) a week were now receiving pensions at the twenty-six shilling or forty-two shilling rate. The effect of these higher pension rates was to increase the expenditure on old age pensions from about £127 millions to about £268 millions a year.

Sir Ernest Rock Carling referred to the National Health Service Act and urged that the old people should be considered. In old age the dividing line between health and

sickness was very narrow, and rehabilitation should be studied in order that beds might be freed. Adequate description of the distressing circumstances of old people in many institutions would need the pen of a new Dickens, and tribute should be paid to the staffs who worked so courageously in distressing surroundings. Dr. Marjory Warren gave a challenging address and contrasted the usual dependence of the aged with the Chinese custom of giving to age the greatest respect, and called for "a change of heart." The problem was not one of poverty, as the aged included all classes in the community. People were living longer, houses and domestic help were much more difficult to obtain, and our mode of life had changed, with a greater instability and mobility of the family, faster transport, wireless, and the different position of women. Children should be taught to respect age, and old people should be regarded as the head of families for as long as possible. The question "Are the old worth preserving?" could be answered on ethical, educational, and economic grounds. The broad medical principles were: full medical and nursing care; long-term treatment of sickness in suitable surroundings; homes with specially trained personnel for all types, including the bedridden; research into diseases of the aged and ageing; and social workers to banish want, loneliness, monotony, and boredom. This called for the unification of authorities and societies interested in the problem, and for the segregation of types of old people needing different treatment.

A MEDICAL PLAY

Mr. Warren Chetham Strode will be remembered for his recent successful play *The Guinea Pig*. His new play, *The Gleam*, at the Globe Theatre, is successful, among other things, in demonstrating that whatever else it may do the future National Health Service Act does not make good theatre. The play is well acted and adequately produced. Mr. John Robinson and Mr. Hugh Kelly, as an established and a newly qualified doctor respectively, give performances which are much more convincing than the usual stage presentations of medical men, though there are some minor medical errors.

What the author has attempted to do is to dramatize the future of national planning, particularly as it relates to the National Health Service. There is much discussion of the difficulties and the disadvantages of the new Act. There is a health centre as it might be in 1949. The doctor who is the principal character believes in the principles underlying the scheme but finds his professional freedom sorely curtailed. There are similar conflicts in the background. Mr. Wyndham Goldie hits off extremely well the reaction of a self-made man when the town-planning of which he approves involves the demolition of his own house. Mr. Harry Ross, as a local councillor and transport contractor, believes implicitly in the nationalization of medicine and in town-planning but objects vehemently to the nationalization of transport. The author has given his best lines to the less important characters, and much of the discussion that goes on has an air of unreality about it. His final answer to the problem of reconciling individual medical freedom with chromium-plated health centres and streamlined planning is that the young doctor, who at one stage is bent on abandoning medicine and turning to farming in Kenya, should join the general practitioner he admires in trying to work what is good in the Service and resist what is bad.

Active preparations are being made for the issue of a third edition of the *World List of Scientific Periodicals*. The last edition of this invaluable scientific reference work, issued in 1934 and covering the years 1900-33, is now out of print though still in constant demand. It contains upwards of 33,000 titles of journals and includes the holdings of some 180 libraries in Great Britain and Ireland. The new edition, which is designed to include all the scientific and technical periodicals that appeared during the period 1900-47 as well as the holdings of additional libraries, will therefore be considerably larger. Librarians are being asked to co-operate as before by sending particulars of all those journals on their shelves that do not appear in the second edition or are shown there as having no location in this country, to: The Secretary, World List of Scientific Periodicals, c/o The Zoological Society of London, Regent's Park, London, N.W.8. Further information may be obtained from this office.

Reports of Societies.

LATE RESULTS OF PARTIAL GASTRECTOMY

At a meeting of the Liverpool Medical Institution on Nov. 7, with Mr. J. B. OLDHAM (Vice-President) in the chair, both the surgical and the medical aspects on operation for peptic ulcer were examined.

Mr. KIRK WILSON mentioned the almost insuperable difficulties in continuing the usual follow-up during the war years, but quoted a personal and consecutive series of 148 cases of partial gastrectomies done for simple peptic ulceration in the years 1934-9 inclusive. In the series 104 had a gastric, 40 a duodenal, and four a jejunal ulcer. Three of the jejunal ulcer cases had gastro-colic fistulae, and in four of the gastric ulcer cases a gastro-jejunostomy had to be undone as the first step in the operation. Over 50% of the duodenal ulcer patients were under 40 years of age, while 65% of the gastric patients were over 40. During the same period, of 117 cases of carcinoma of the stomach, 48 were submitted to gastrectomy. In the high gastric ulcer, the size of the crater, the degree of penetration and fixation, and the failure to respond to medical treatment were the main indications for operation. Ulcers of the pyloric antrum and canal were treated surgically without undue delay on account of their tendency to undergo malignant metaplasia. The main indications for operation in duodenal ulcer were repeated perforations and recurrence of symptoms after several courses of intensive medical treatment in hospital. The Polya-Moynihan operation was done for 44 patients, the Hofmeister operation for 45, and the "physiological" for 59. The over-all mortality was 8%. In exactly half of these deaths necropsy showed that the cause of death was pneumonia and that healing had occurred without infection in the peritoneal cavity. One pulmonary embolus was recorded, and in three cases in which permission for a post-mortem examination was unobtainable it was suspected that a leak from the duodenal stump had occurred. In more recent series the mortality and morbidity had been much reduced by (1) more intensive pre-operative preparation to correct minor degrees of anaemia and hypoproteinaemia, and (2) the recent phenomenal advances in anaesthesia. The relaxation obtained with *d*-tubocurarine chloride compared very favourably with that produced by a perfect spinal anaesthetic, and after this drug chest complications had not caused any anxiety. The importance of medical supervision in the more remote post-operative period and the value of a properly organized continuation clinic were emphasized.

Medical Point of View

Dr. ROBERT KEMP said that he hoped there would be no "surgery versus medicine" trend in the discussion, for the surgeon operated only on medical failures and the physician only saw the bad results of surgery. The physician must have clear-cut indications in his own mind, must know the risks and drawbacks of operation, and must follow up the late results. In most complicated ulcers and many gastric ulcers the indications for partial gastrectomy were clear, but in duodenal ulcer it was an individual clinical decision as to when the lesion was beyond permanent help from medical treatment. Apart from the immediate post-operative risks there were those of later stomal ulcer, pulmonary tuberculosis, anaemia, small stomach, and dumping, with lassitude, malnutrition, gastritis in the stump, and the need for further dieting. From a series of 148 consecutive partial gastrectomies done by Mr. Kirk Wilson between 1934 and 1939 71 patients traced in 1946 were reported as 55% excellent results, on full work and full diet, and with no significant symptoms; 28% showed good result, full work, and good health, but needing a modified diet; 17% showed fair result, in that despite dieting they still had some symptoms and lost some time from work. In every patient seen there had been a definite improvement on the pre-operative state. The results in duodenal ulcer cases were particularly good, but despite this it was still the physician's duty to keep his patient to a regime strict enough to obviate the need for surgery. If, however, he failed in this the operation should be done under optimum conditions with full preparation and convalescence in the medical wards.

To soothe and smooth harsh dry hands

More than most people, a doctor must be fastidious about his hands. Yet frequent contact with water and antiseptic solutions tends to rob the skin of its natural nourishing and lubricating elements. The regular use of Nivea helps to keep the skin in good condition. Nivea Creme possesses two unusual qualities. It is an emulsion of water suspended in oil; and it contains "Eucerite", a mixture of solid alcohols very closely related chemically to the fatty substances present in skin secretions. Nivea is therefore able to penetrate to the tissues beneath the surface and replenish any deficiency of the skin's natural oils.

- Keeps the skin smooth and soft.

- Relieves sun and wind burn.

- Prevents babies' napkin rash.

- Soothes after shaving.

- Softens chapped Hands.

- Relieves bed sores.

NIVEA CREME

In special medical packs of 1 lb.

For professional and dispensing purposes.

The Modern Surgical Dressing

'Elastoplast' is valuable in the treatment of sprains, wounds, and varicose conditions. As a dressing, it affords protection to newly-formed granulations, and should be allowed to remain undisturbed as long as possible, provided no unusual pain is experienced.

Elastoplast

TRADE MARK

BANDAGES AND PLASTERS

Made in England by T. J. Smith & Nephew Ltd., Hull.

REMINDER: Smith & Nephew Plaster of Paris Bandages now carry the universal Trade Mark 'GYPSONA'

For Pernicious Anaemia 'PEPSAC'

Brand
DESICCATED STOMACH SUBSTANCE

A HIGHLY active preparation of desiccated stomach substance for oral administration in the treatment of pernicious anaemia. Clinical results have shown that Pepsac is an excellent maintenance treatment and is the preparation of choice in the prophylaxis and treatment of sub-acute combined degeneration of the cord.

To combat the Depression of Chronic Organic Disease

Many patients with chronic organic disease sink into a persistent depression, characterized by discouragement and even despair. Unless effectively combated, this depression may intensify the symptoms of the basic disorder and handicap its treatment. By restoring optimism and interest in useful living, 'Benzedrine' Tablets frequently help to overcome prolonged depression accompanying chronic illness and thus facilitate the general management of the case.

Each tablet contains 5 mg. 9-aminopropylbenzene sulphate (amphetamine sulphate)

BENZEDRINE TABLETS

Sample and literature sent on the signed request of physicians

PROGESTIN B.D.H. and ETHISTERONE B.D.H.

Progestin B.D.H. is identical with the natural hormone of the corpus luteum. It is administered by intramuscular injection in all conditions in which a rapid progestational response is required, particularly threatened and habitual abortion, menorrhagia and metrorrhagia. Minor degrees of luteal insufficiency may be corrected by oral administration of the synthetic analogue Ethisterone B.D.H. Further details are available on request.

DERIPHYLLIN

THEOPHYLLIN and DI-ETHANOLAMINE

indicated in

**Cardiac Decompensation, Oedema,
Angina Pectoris and Cardiac Asthma**

Deriphyllin has a regulating action on water metabolism and influences the cardiac mechanism. By dilating the coronary vessels and relieving any coronary spasm which may be present an improved flow of blood through the heart-muscle is secured.

Deriphyllin is exceedingly well tolerated and may be given for a long time (chronic cardiac decompensation) without reaction occurring. Effect does not decrease after prolonged administration. Can be usefully combined with the organic mercurial diuretics. Not contra-indicated in renal disease.

Deriphyllin-Strophanthin is indicated for all cases of heart failure.

Available in liquid form for oral use,
ampoules and suppositories.

Literature and samples on request.

CAMDEN CHEMICAL COMPANY LIMITED
NORTHINGTON HOUSE, NORTHINGTON STREET,
LONDON, W.C.1

Analysis of a Further Series

Mr. COSBIE ROSS discussed a series of 160 consecutive gastrectomies. Eight of these patients (5%) died as a result of the operation: three from myocardial failure, three from bar pneumonia, one from pulmonary embolus, and one during the operation. Three patients died at a later date: one from carcinoma of the oesophagus, one from carcinoma developing in the stomach sac, and a third from a perforated stomal ulcer a year after gastrectomy, previous to which he had perforated on two occasions. Of the 55 cases followed up, 47 were extremely grateful, and of the remaining eight, one had advanced phthisis, one had syringomyelia, and six, although improved, had mild dyspeptic symptoms. No one complained of even a moderate degree of pain. The short afferent loop in making the anastomosis was important. Recent experiments had shown that the daily intramuscular injection of 30 mg. of histamine-base in beeswax into laboratory animals caused a torrent of acid secretion, and in gastrectomised dogs always produced a stomal ulcer when a long afferent loop was used (never with a short one); and the anastomosis should be stercolic close to the duodeno-jejunal junction.

Series from University Department of Surgery

Mr. A. CLIFFORD BREWER reported on some 362 partial gastrectomies for duodenal ulceration. One fact was pre-dominant: subtotal gastrectomy, with removal of the whole pylorus and combined with the use of a Hofmeister stomach, yielded excellent results, but results were by no means so good when the pylorus was left behind. A two-stage operation in difficult cases appeared very satisfactory so long as the second stage followed within twelve weeks.

IMMUNIZATION WITH HUMAN BLOOD
DERIVATIVES

Dr. WILLIAM GUNN delivered his presidential address before the Fever Group of the Society of Medical Officers of Health in Nov. 8, dealing with the advances during the last twenty years. He briefly described the various methods of withdrawing, harvesting, and storing plasma and serum. The loss of protective potency of serum with age, appreciable in less than 1 year even when stored at 4°C. and due apparently in large measure to the presence of denaturing enzymes, had been countered by freeze-drying *in vacuo*, whereby further loss was probably averted as in the fourteen-year-old sample exhibited. As preservatives tended to interfere with the drying process, various substances had been tried, with the result that phenol, originally selected as the one of choice, was retained as possessing the best all-round antiseptic action; the time taken in drying was only slightly lengthened provided that the ratio of the total volume to the surface area was kept low. The only real disadvantage incidental to the use of phenol was that it could not be added to serum in stronger concentration than 5% without causing coagulation of the proteins.

Homologous Serum Jaundice

No proved cases of homologous serum jaundice had been encountered in some 20,000 administrations, but the long incubation period and the difficulties of follow-up in a large area such as London had to be considered. In recent years donors had been supervised for four to five months after the withdrawal of blood, but sub- or non-icteric hepatitis remained a possibility which even repeated blood counts and van den Bergh tests might fail to demonstrate. There was insufficient evidence to show that antiseptics, drying, or even heating to 57°C. for 4 hours, as had been done on gamma globulin specially stabilized for this purpose, were effective in neutralizing the causative agent in homologous serum jaundice; probably the complicated physico-chemical processes involved in the separation of human plasma proteins into their constituent fractions alone sufficed.

A strict age- or weight-adjusted dosage (e.g., 0.1 ml. per 1 lb. (0.45 kg.) bodyweight recommended for gamma globulin) did not agree entirely with common experience. At ages 0-1 year

and 3 years upwards the effectiveness of the prophylactic against measles tended to be artificially enhanced compared with the relatively susceptible 1-3 years group, and something over the average dosage was needed if protection was regarded as imperative.

Convalescent Sera

The appropriate dose of convalescent rubella serum which had been collected for purposes of prevention in women in the early months of pregnancy was not yet determined, but probably lay between 10 and 20 ml., depending on the interval between the date of exposure and time of injection. Preliminary trials had shown the protective titre to be rather lower than was usually found in the measles antiserum, possibly because the infection stimulus was less intense. The gamma globulin fraction would naturally be much more effective, approximately twenty-five times more potent, as had been reported in trials of mumps convalescent serum by S. S. Gellis, A. C. McGuinness, and M. Peters (*Amer. J. med. Sci.*, 1945, 210, 661).

PROPHYLAXIS OF ERYTHROBLASTOSIS FOETALIS

At a meeting of the North of England Obstetrical and Gynaecological Society, held at Sheffield on Nov. 1, Dr. C. C. BOWLEY said that the erythroblastotic infant arose once in less than 300 labours, and had a mortality rate of nearly 80% if untreated, while 10% of those infants who did recover were affected by central nervous system lesions or hepato-splenomegaly. Erythroblastosis foetalis should be anticipated by the routine Rh typing of the blood of every pregnant woman, and where the woman was Rh-negative an examination of the blood for the presence of atypical agglutinins should be carried out at the eighth month in primigravidae and at least once before the eighth month in multigravidae. Previous transfusion should be considered as having the same effect as a pregnancy, and all emergency transfusions should be carried out with Rh-negative blood. On the discovery of atypical agglutinins their titre should be determined and re-determined each month until delivery, and monthly titres were needed in every multipara with a definite history of children affected by erythroblastosis foetalis. Vitamin K should be given to the Rh-negative mother before delivery. It was effective if taken orally, combined with the administration of bile salts to break up the fat vehicle and to obtain maximum absorption as little as four hours before delivery; when given to the child it should be in a watery solution and administered by intramuscular injections. Blood transfusion with a fresh Rh-negative red-cell-concentrate should be effected early.

A meeting of the Chelsea Clinical Society was held at the South Kensington Hotel on Oct. 8, the title of Dr. Ronald Jarman's presidential address being "Modern Anaesthesia." Dr. Jarman gave a comprehensive review of the history and latest developments in his specialty, and an interesting discussion followed in which many members joined, these including Dr. Archibald Marston, Dr. Hancock, Mr. Ivor Back, Mr. Michael Smythe, and Dr. Carnac Rivett.

The 44th annual meeting of the Medical and Dental Defence Union of Scotland was held recently in Glasgow, with Prof. T. K. Monro as president. The report of the council showed that during the past year the membership had increased by 279, and the number of members on the register was now 5,742. The financial position continued to be strengthened, notwithstanding the waiving of subscriptions from members in H.M. Forces—a concession which is to continue for the current year. It was stated that cases continue to arise in which the lack of proper records makes the defence of claims more difficult. This is specially noticeable where casual dental patients are concerned. The Union impresses on its members the need for careful records of consultations, treatments, appointments, and telephone calls, together with all information on the progress of cases. In particular, if a certain line of treatment is advised, but rejected by the patient, the fact should be noted. Such records, being contemporary evidence of what transpired, are of great value in the event of a dispute arising at a later date. The Union participates in the work of a joint co-ordinating committee with the two defence societies which have their headquarters in London.

Correspondence

Statistics in the British Zone

SIR,—On behalf of unofficial vital statisticians I thank you for your two articles on conditions in the British Zone in Germany (Nov. 30).

If one averages the death rates of your Table II on page 827 we have 14.3 per 1,000. The rate of mortality in the first six months of a calendar year is higher than in the second six months, so this is (other things equal) an overestimate, but we may take it. As you point out, gross rates of mortality of that order were common enough in England and Wales a generation ago. But then the rate of infant mortality was often higher than that recorded for Germany in the first six months of 1946 (99.5 per 1,000 live births). In 1912, however, the rate of infant mortality in England and Wales was 95 per 1,000 live births and the gross rate of mortality 13.3 per 1,000 living. This, however, cannot properly be compared with the German figure because in 1912 the birth rate in England and Wales was 23.8 per 1,000 while in Germany in 1946 (six months) it was only 14.6. Had the latter been the rate in England and Wales in 1912 the death rate would have been about 12.6 instead of 13.3. It is also possible that in general the age and sex constitution of the German population was more favourable to low mortality than that of England and Wales a generation ago, because the fall in the birth rate in Germany lagged behind that in England and Wales, and so the optimum constitution may have been reached later. I do not know.

On the other hand there are factors which would artificially raise the death rate in Germany. (1) Many men of military age are prisoners of war; their absence may not be compensated by an influx of workers to the Ruhr. (2) The immigration into the British Zone of refugees "in very bad condition." The statistical effects of these can only be guessed. We do have left a terribly wide field for emotional conjecture. Of course a statistician always asks for more data and sometimes forgets how hard it is for overworked officials to collect them. I do not; but I still press for a census of the population by sex and age and for tabulation of deaths by age, sex, and main causes.

We may, I think, safely believe that in the first half of this year the rate of mortality in the British Zone was some 10–15% higher than in England and Wales a generation ago. Death rates are not perfect indicators of human conditions—a low death rate is compatible with great misery—but they are the easiest to measure accurately. Sample surveys of weights are valuable, but need explanation. One weighs all at work in a factory on Jan. 1 and repeats the observation on Feb. 1. The two sets will not generally be all the same people owing to sickness-absence and labour turnover.

I am *not* suggesting that our colleagues in Germany do not know these elementary facts, only that the detail of operations should be published; otherwise partisan criticism is inevitable. We as a profession are the last people in the world to forget Walter Bagehot's saying: "How much of real suffering is there that statistics can never tell." But we do know the value of statistical indices.—I am, etc.,

Loughton,

MAJOR GREENWOOD.

Physiological Rest

SIR,—It is good to find Mr. Norman Capener (Nov. 23, p. 761) giving fresh publicity to the views of Hugh Owen Thomas and Sir Robert Jones, views which often now get lip-service but whose fundamental principles are apt to be obscured by a mass of excrescences. I would ask your courtesy to supplement Mr. Capener's thesis by a few suggestions of modern improvements.

For instance, he illustrates two pieces of apparatus to abduct the shoulder, but omits the very simple device of balancing the wrist on the top of the head by a wristlet fastened to a webbing cap of the type used by footballers. This is adequate in nearly all cases of deltoid paralysis and avoids putting the weight of metal apparatus on hip muscles, which are commonly weakened simultaneously.

Then the rather complicated finger and wrist apparatus which he illustrates can nearly all be replaced by "perspex" (bomber

glass) moulded either to the limb or to a plaster model. Unlike leather apparatus it needs no metal struts, while it is more readily moulded in several planes than is the equally light "vulcanite." The physiological position of thumb and finger in opposition and moderate flexion can be maintained by simple roll of "perspex" about the size of Churchill's cigar. If the long extensors are weak, the roll can be made about 2 in. (5 cm.) in diameter, and these are almost self-retained steadied by a tape round the wrist.

Plaster of Paris, which is recommended for many conditions has numerous drawbacks, one of the chief being its weight and, as the author points out, the ease of its application does not imply that it is easy to apply well; and it is in these days a common source of much human misery. The hand splint illustrated, while maintaining a good posture, cuts out a active function, whereas the "perspex" roll already referred to enables many actions to be carried out by the thumb and fingers, while still maintaining good posture.

Similarly, scoliosis of the type illustrated can be more comfortably supported by a buttress of "perspex" or of compressed celluloid attached to an ordinary ladies' corset; and these have the advantage of filling out the hollow so as to give a better set to the clothes. The Goldthwait spine brace, which is constructed on the same principles as the Taylor brace, has the great advantage that, being made of spring steel, it is more supple, allowing rotary and lateral movements without antero-posterior ones.

For the knee, where movement is to be eliminated but no weight-bearing, as in chronic arthritis, a moulded posterior trough of "perspex" is light and efficient. Where later instability needs control but flexion is desired, the trough for calf and thigh can be separate and joined by a pair of light steel hinges.

One agrees heartily with Mr. Capener's warning against the evils of the bed posture commonly seen in hospitals, but regrets that he did not refer to the extreme value of the prone position with the chest supported on a firm wedge; this allows exercise of the glutei, spine, and lateral abdominal muscles in a shortened position, which builds them up astoundingly in such cases as poliomyelitis and quiescent tuberculosis of the spine. One feels a little nervous at the mention of "regional surgical workshops," for though this is in line with the principles of the National Health Act, there has in each of the great wars been a good deal of standardization under the general supervision of master orthopaedic surgeons. But the great need at present, as stressed not long ago by Professor McMurray in his presidential address to the British Orthopaedic Association, seems to be to induce the younger generation of surgeons to devote time and interest to fitting their appliances to the needs of individual patients and specific types of diseases—e.g., something which may be admirable for a foot-drop of lower-neurone origin may be quite harmful in one in a spastic cerebral palsy.—I am, etc.,

Bath.

M. FORRESTER-BROWN.

The Plebiscite

SIR,—I was disturbed to find in the *Journal* of Nov. 30 letters suggesting, for a variety of reasons, that we should answer "Yes" in the referendum. They seemed to me to be evidence of muddled thinking. There was the point of view expressed that there could be no harm in discussing regulations *without prejudice*. If we discuss them at all we imply acceptance of an Act with which we have expressed our profound disagreement and we know from his own lips that Bevan is not prepared to enter into negotiations with us. We also know into what position our discussions—*without prejudice*—on the matter of "compensation" manoeuvred us. Why, then, should we delude ourselves?

Again, there was the point of view expressed by some that the National Health Service Act is now law, that the Government were given a mandate by the vast majority of the country to make it law, and that, even if we consider it to be a bad law, we should not oppose it but obey it and co-operate with its framer. I have even heard the view expressed that Socrates drank poison at the instance of the laws of Athens, which he obeyed though he thought them evil, and that therefore we should follow his example. Here is an analogy indeed! Are we too to commit suicide? It is more than doubtful if

overnment had any mandate at all from a majority of the people as regards the National Health Service Act. The "vast majority," even yet, are largely ignorant regarding most of its details, and if they were not would probably be horrified at a good many of them.

There are inherent in this Act a definite and deliberate attack on personal liberty, an obvious urge to dominate, oppress, and control—a step not unlike some of those first taken by a man named Adolf Hitler. If we believe that Act to have in it the seeds of future evil—evil not only for ourselves but for our children—for freedom's sake let us say so and stand firmly together. Had there been people in Hitler's Germany who, at the beginning, had had the courage to say, "These things are bad; we must and shall oppose them!" and not, "These things are the law of the land, so we must obey lest we get into trouble," Belsen and Dachau might never have existed and the second world war might never have happened.

In any case our fighting Chairman, Guy Dain, has surely made it clear that there is nothing in the Act which says we must join a service of which we utterly disapprove, and we break no law by not doing so. Let us remember that, and remember too what we have already gained by unity and courage; and let us, for the honour of our profession, retain that courage and unity for the battle which lies ahead of us.—I am, etc.,

A VICTOR RUSSELL,
Chairman, S. Staffs Division, B.M.A.

SIR.—Fears which I expressed in a recent letter to you—that some, possibly many, doctors who replied "Yes" to the question asked in the plebiscite would, if they had understood the report of the question fully, have answered "No"—have proved to be far from groundless. At a recent meeting of my local Division, called to discuss the matter, it was obvious that a number of men had already replied "Yes" under a misapprehension, and it was indeed pathetic to sit there and realize more and more as the meeting went on that if only the plebiscite question had been better worded the replies would have been (I estimate) 95% "No."

The root cause of the trouble appears to have been that so many men have probably not had the leisure in which to read all the discussions and articles which have been published in the past few weeks. When finally the blue paper arrived, thoughtfully accompanied by a 2½d. stamped envelope, they opened it full of enthusiasm, expecting (rightly) a simple question to be answered. The word "negotiate" misled them. And, feeling that all fair-minded men should be at least willing to negotiate, they fell into a trap (unintentionally placed before them) and replied "Yes."

Dr. N. Beattie (Nov. 30, p. 834) makes the good and obvious point when he expresses the opinion that in this plebiscite we should have been asked simply and straightforwardly whether we were willing to work the Act as it now stands on the statute book. Brief notes in block letters explaining that this would mean giving way completely upon certain very important points, already decided by the majority of doctors to be indispensable in an Act, might well have appeared on the form. Is it too late now to publish in a prominent position in the *Journal*, or to circulate to doctors, a request for a reconsideration and a further reply bearing these implications in mind? I suggest that the number of "No" replies would be thereby largely increased.—I am, etc.,

A. W. R. EARDLEY.

Coine.

SIR.—Having taken a more active part in the controversy over the National Health Service than your correspondent, Dr. L. P. Lockhart (Nov. 30, p. 835), I would like to comment on some of his views. Many discussions with members of the public have convinced me that they are only concerned with the formation of a unified service free of doctors' bills. They do not realize that our opposition has never been against this—indeed the contrary is the case—but is directed against the "nationalizing" of the profession, which is necessary for the Government to obtain control of medical certification.

Your correspondent stated that we must not let our "interest" be jeopardized without a struggle, and yet, having looked at the far horizon and seen streams of lava flowing from many political volcanoes, he seems to advocate a jump into our local volcanic stream in order to attempt to direct its flow. I would

suggest that we may be able to do something from outside, but once in the stream we shall be engulfed and helpless.

I agree that the Minister may be different now his Bill is law, and will formulate regulations which will probably be attractive, especially financially. He will then proceed, at a later date, to modify them as conditions make the profession more "ripe for plucking." Mr. Bevan has ignored the views of our representatives from the first, although he tells the public that he has been in "consultation" with us. We are his technical staff upon whom he will rely for the success of his Bill. This does not seem to me to be a democratic procedure but is the action of a Minister who knows no compromise.

Dr. Lockhart asks what we should say if a union held up the work of the country because it did not like an Act. This is of course a likely form of reaction and seems to be the only language the Government will understand. However, I must point out that, should the majority refuse service at a later date under the new Health Act, we shall continue to serve the public, but not under the terms of the Act—a vastly different thing from "holding up the work of the country."

May I refer to the "principles"? These have been formulated by representatives briefed by each Division, and Dr. Lockhart may have a hand in the briefing of his own representative. A reply to the plebiscite of "Yes" will imply that the individual is prepared to throw the principles of the profession overboard if the regulations are sufficiently attractive. This implication is inescapable and to my mind was not made sufficiently clear in the literature sent out with the plebiscite form. Our principles are sound and reasonable and their incorporation in the Act would have left us free and would still have given the people the service they wished. Let us stand by our principles, and our prestige will suffer far less than if we become Mr. Bevan's yes-men.—I am, etc.,

Rotherham.

ALAN TAYLOR

SIR.—The reason why I have answered "No" to the plebiscite form is not from a desire to "slam any doors" but because I consider the National Health Service Act to be another nail in the coffin of the freedom of this country. Under the Act my life, in the long run, would probably be very much easier. I would, in the ultimate future, enjoy the benefits of a fixed—or nearly so—income, regular hours of work, a rota system of night work, locum arrangements for holidays, fewer practice expenses, etc., but, as I have said to many ardent local Socialists, I went into medicine and general practice with my eyes wide open, and if I was not prepared for irregular hours, night work, and being "on duty" for 24 hours a day I would not have taken on the job.

As the Bill is now law, we can only discuss details such as terms of service, which can be altered without consultation and irrevocably at the whim of this or any other Minister, and if we answer "Yes" it means that we tacitly accept the Act except for certain details, and from then on we are powerless in the hands of the Minister.—I am, etc.,

Coventry.

JOHN HALE POWER.

The New Health Service

SIR.—It has been with some dismay that I have recently read in the popular press of the tendency in the ranks of organized Labour for interference in matters strictly medical. While a great number of us do agree and even welcome a medical service that will guarantee equal service to all, irrespective of rank or position, I do think that I speak for the majority when I suggest that the time has come for us as an organized body to call "halt"—resoundingly and meaningfully. To think that an organization like the T.U.C. dares to meddle in our affairs is almost, with due respect to all forms of religion, blasphemy.

I am a member of the Labour Party, but I do not admit that this or any other party has the right to regulate the actions of a humanitarian body, which is concerned solely with the well-being of all people living in these islands. Isn't it about time we simply stated an irrefutable fact? We are the persons who are looking after the health of the people, and we do not care very much about the idea of lay people interfering with our ordinary functions. Why don't we say to the responsible Minister, "We are quite willing to play ball if you are willing to accede to our demands"—not requests? This

would show him quite definitely that we want our own terms, under our own organization, and unless we get our own terms he will have a very pretty Act on the statute book which will mean nothing if he has not a medical backing.

Being a Celt, like the Minister, I would like nothing better than a tussle with him on this question, and if I were guaranteed the support of the medical profession I am sure that I could, like many a delegate in a labour dispute, gain the dispute's (horrid artefact) point. I do think that if a few of the younger members of the profession were allowed to dictate for the rest of us (not arbitrate, please note) we could follow the fashion in labour disputes and get our point at the expense of the ordinary taxpayer.

So far as an ordinary country doctor can see, nothing has so far been done in the ranks of medicine that will assure the Minister of any definite opposition. I personally would be very glad to see an ordinary practitioners' association being formed with the avowed intentions of (a) a reasonable resistance to sterile acceptance of Government proposals (i.e., without full discussion among general practitioners), and (b) making quite sure that we as a profession shall have the last word about the running of any such scheme. Might I here remind readers that the most stringent medical discipline in all the world is maintained in Great Britain, and this same discipline is maintained entirely by the profession. Surely this in itself is enough to guarantee any services run by medical men in this country.

In my humble opinion now is the time for us to unite and tell the Government what we are willing to do, for the good of the population—but only at our own terms. I am of course writing as an ordinary general practitioner, and would suggest that other branches of medicine should formulate their own demands. In this way, and in this way only, can I see satisfaction for the general public and for their servants, the medical men and women of these islands.—I am, etc.,

Llanrwst.

MEURIG W. WILLIAMS.

Profession or Trade?

SIR,—During the past year I have talked with many medical practitioners and read many letters in the *Journal*. I find that many men of the finest type are prepared to enter the new Health Service, even though they disapprove of the Act as it stands, because they consider they should be prepared to make personal sacrifices if there is any hope that the ultimate service to the patient will be improved. Their attitude has developed because they have been "conditioned" by many years of work in which they have always put the needs of the patient before self-interest. While we may doubt whether the ultimate good of the patient will be achieved by the present Act, we must honour the integrity of their opinion.

Nevertheless, events of the past week must have shaken all those who think this way. If the principle of the "closed shop" can already be applied to doctors and nurses, then will it not be applied at a later date to those who enter the Health Service? Coercion of individuals into a political organization of any colour is so abhorrent to our deep-rooted conception of democracy and the freedom of individual thought that the present situation must give us reason to consider with deep concern where acceptance of service will lead us. Let us take heed lest we relinquish that freedom which we can never again regain, and so become enslaved in a political tyranny only too similar in its beginnings to that which brought the world to chaos seven years ago.—I am, etc.,

Kendal.

GEORGE H. EDGEcombe.

SIR,—Servants of our patients or slaves of the State?—that is the question. The present is the time to make a last stand against the Nazi creed that the individual exists for the State. We fought for six years against this pagan ideology and were the only nation with guts enough to declare war while lesser nations thought to negotiate with tyrants and were swept away. To beat the enemy we employed methods of "total" war, but now the devil of totalitarianism refuses to depart. To-day our Parliament, elected by a vast majority, is ordered by Blackpool and Brighton. The Socialists have captured the Labour machine, and to ensure complete subservience they have engineered the "trade" unions into political unions and are

crushing political independence among the workers by means of the "closed shop."

Medicine should be divorced from politics, but we have been thrust into the van of the fight, because a doctor's certificate may provide a loophole for a labouring man to escape work direction to other places. To prevent this possibility doctors are to be brought to heel. That those in power at present do not trust us in this matter is shown by their attitude over the "milk priorities" certificates. Our patients' needs are to be subservient to the State.

How are we being tempted? We are being given an Act which is welcome to most doctors, including myself, as it provides many of those improvements in services for our patients for which the profession, through the B.M.A., has been fighting for years but without avail until the National Government took up the question. The tragedy is that it has fallen to the lot of a party Government to hammer out the Bill. Look at on its own it has enough attractions to tempt some doctors to say "Yes" to negotiation over details. But others with wide vision can see clearly that the Health Act contains within the makings of a prison for our patients and ourselves which linked up with the other pieces of the political jigsaw puzzle and have refused to be tempted at all.

How are we to be coerced? The methods of coercion are clear. Now that the Act has been passed, fifty nurses and doctor at the Willesden Municipal Hospital receive dismissal notices because of refusal to join a trade union. It is reputed as a mistake, which it undoubtedly was, for the Press has not yet been muzzled (in spite of the venomous intolerance a free press shown by some of the speeches for the motion demanding a Royal Commission on the press), yet this pretence unmasking of intentions has been repeated at Walthamstow.

Mr. Bevan has told us that we are not yet "ripe" for plucking. These are ominous words both for our patients and ourselves, for although Parliament makes statute law it delegates the making of regulations to the various Ministers. The Minister of Health is given control of municipal and voluntary hospitals. But will the patients of a doctor who remains outside the Service be easily admitted to a State hospital? And if nursing-homes become State controlled by regulation will they happen to private practice?

What can we do about it? The Bill is law, and the defeatist says, "Let us make the best of it by negotiation." Was this Churchill's answer to the Nazis? Laws are man-made, and men make bad laws they can make new and better ones. When Australian doctors were presented with a similar Bill they believed it bad they refused to work it: it lies dead in the Australian statute book. It may take only a six-week electioneering campaign to make a politician but six years to make a doctor, and Mr. Bevan admits that the Act cannot work without our co-operation. Let him bring forth a Bill worthy of our patients and not a travesty of justice for their enslavement at the turning of our profession into a trade.—I am, etc.,

Derham

E. IVIMY PUDDY.

So Now You Know

SIR,—As a visitor to this country from Australia I have been particularly interested in the development of thought on the subject of a State medical service controlled by politicians. Members of the profession have been divided in their views: some in favour of a State service as being the only means of giving the public the best treatment, others reluctant to let the profession pass into the hands of politicians.

The recent action of the Willesden Borough Council in dismissing the staff of two hospitals for political reasons clarifies the position. In any service which is, or can be, controlled by the Labour Party, of which the ruling body is the Trades Union Council, doctors and nurses—otherwise quite competent in their work—can be sacked for their political views. Such a state of affairs has never existed in medical history except in Nazi Germany.

No matter how much the action of the Willesden Borough Council may be condemned by the Parliamentary Labour Party no matter whether the notices of dismissal are withdrawn in this instance, it is now obvious that the T.U.C. intends to force us to join a union—a body associated in the minds of most of us with the coal face, railway employees, and un

killed labourers, and controlled by the votes of these large nions. Mob rule has no place in medicine. The future is now s clear as it was to Churchill in 1938. And if your Negotiating Committee "flies to Munich" to barter with Bevan, you ave only yourselves to blame for the degradation to which ur profession will be subject.—I am, etc.,

Penn.

JAMES SMIBERT.

Unswerving Support

SIR,—If only we would all sink minor differences and stand ogether we could obtain from the Government any terms we ke within reason. As Mr. Bevan stated, the co-operation of he medical profession is essential to the working of the scheme. No doctor should agree to join unless the right of appeal to he courts of the country is granted. This is, in my opinion, the most vital part of the whole Act.

If any doctor joined the Service and then found conditions ntolerable and wished to retire, he would be permanently revented from practising in the locality where he is known nd has some prospects of making some kind of living, and it ould be almost hopeless for him to try elsewhere. He may ave bought, built, or altered a house to suit his professional equirements. The house may in ordinary times be most un-uitable to anyone but a doctor owing to its size, construction, r situation, and yet he, his widow, children, or even grand-children may render themselves liable to heavy fines and mprisonment if they sell the house to another doctor.

The present danger is apathy and the idea spread by the lay press that just because the Act is law nothing can be done. am ringing up a few of my colleagues who do not attend neetings and drawing attention to these and other dangers in he Act. Emphasis should be laid on the successful fight put up by our fellow-practitioners in both Australia and New Zealand. Some practitioners seem to have been confused by he manner in which the plebiscite question was framed. They ave informed me that they answered "Yes" and they "always believe in discussion and arbitration" but that they would not n any account join the proposed Service on the terms and onditions laid down in the Act.—I am, etc.,

Rainham.

W. U. DESMOND LONGFORD.

The Profession and Trade Unions

SIR,—It must have come as a profound shock to doctors and urses to find that future employment might depend on their eing members of a trade union, which I presume would have to be recognized by the T.U.C. It seems outrageous that our profession, which should be without interference by petty trade union and political controls, should be subjected to this dictatorship and political prejudice. This type of thing gives us a foretaste of what the profession may expect in a National Health Service.

Let us hope that the British Medical Association will give a clear call to the profession to resist with all in its power this flagrant intimidation into trade union membership, and let the Association give all the publicity it can to our fight for principles and freedom. Our work, our service, and our conscience must be governed by our duty to our patients and not by any trade union or political theories and preachings.—I am, etc.,

Newport.

A. B. TAYLOR.

Public Relations

SIR,—Though the individual doctor may be liked, the same can hardly be said of the medical profession as a whole. We do not enjoy a good Press. But now is our chance to correct this anomaly. We shall not, however, win favour by doing what we think the public thinks we ought to do, nor need we harp too long upon the refrain, "We won't let our patients down." The motif behind this pious slogan, though doubtless sincere, may yet be tainted by a tincture of cowardice or sentimentalized by a desire to appear in the guise of Prince Charming.

Surely, Sir, all we really need to do to enlist the support of a strong body of men of good will is to stick up for the interests of medicine itself, and for those ideals which have been evolved by a hundred generations of our predecessors and which are at

present in our keeping to cherish or let go. When old Polonius summed up his advice to his son in the famous words, "This above all: to thine own self be true, And it must follow, as the night the day, Thou canst not then be false to any man." he might have been addressing our profession to-day.—I am, etc.,

Buxted.

W. R. E. HARRISON

Pay of Pathologists and Bacteriologists

SIR,—Nobody will disagree with "Laboratory Doctor's" argument (Nov. 30, p. 836) that pathologists are specialists and deserve an adequate salary, but it opens the wider question of whether specialists should receive a higher remuneration than general practitioners.

(1) I believe that the only inducement to specialize should be a special interest or aptitude in a certain branch of medicine, not the hope to make a lot of money. (2) Perhaps not the modern panel doctor, but certainly the old "family doctor," was a highly specialized person. He was interested and specialized not in diseases but in his patients, whom he knew inside out and had observed from birth into old age. I doubt if "Laboratory Doctor" would be able to take his place to the satisfaction of all concerned. (3) It is very questionable if at present the income of the average specialist is higher than that of the average G.P. In a salaried service the personal prestige will be closely linked with the income. If we agree with the first two points there can be no reason why the specialist should have a higher prestige than the general practitioner, and both should have equal standing and income. Only thus can we assure the proper selection of "specialists in diseases" and "specialists in patients."

I may add that I am a pathologist for the same reason as "Laboratory Doctor."—I am, etc.,

London, N.W.2.

GERHARD BEHR

Rhazes and Avicenna

SIR,—In his paper "The Cough Syrup" (Nov. 16, p. 735) Dr. E. M. Boyd writes: "Arabian physicians, especially Rhazes and Avicenna, are usually credited with introducing syrups. . . ." As they were two of the most distinguished Mohammedan physicians of the Middle Ages (their textbooks, translated into Latin, were used as far west as Montpellier), it is only fair that their native country should have the credit for them—Persia. Rhazes was born 6 miles from Tehran, and the West named him after the town (Ray or Ragae). He lived in Persia most of his life, until indeed he went to take charge of the hospital at Bagdad. Avicenna was born in Central Asia of a Persian father, but worked and died in Persia. They wrote chiefly in Arabic, the scientific language of their day and region, just as Latin was in mediaeval times in Europe, but also philosophical works, and Avicenna one on the pulse, in Persian. (I have a manuscript copy of this.) The Arabs, avid of knowledge and industrious translators of Greek medical and other texts, produced few physicians of note. "Arabian" medicine was largely the work of Persians, Jews, and Syrians.—I am, etc.,

Droitwich.

A. R. NELIGAN.

Seminological Investigations

SIR,—Might one appeal through your columns to pathologists throughout the country to establish a more expert and uniform service for undertaking seminological investigations? The investigation and treatment of female infertility has advanced greatly within the last few years, but many of the excellent gynaecological advances are made ineffective on account of inadequate investigation and treatment of male infecundity. It is now accepted by authorities that in nearly one-half of the barren marriages some infertility is contributed by the male, and in perhaps one-fifth of all cases the causative factor lies exclusively with the husband. The fact that healthy young males who give no history of a genital lesion frequently produce an azoospermic semen or one where the proportion of abnormal sperms is excessively high and their viability too short implies a very serious need not only for adequate diagnosis but for the study of the as yet almost unexplored subject of treatment. If more laboratories would give better service in this work and would agree to make their reports in

a more uniform way it would greatly encourage the clinician in exploring the important matter of therapy.

For the last eighteen months the Family Planning Association has run a laboratory entirely for the purpose of making semio-logical analyses and of studying post-coital cervical mucus. The laboratory is now working beyond capacity, and the physician in charge is willing to accept part-time clinical assistants and a certain number of Grade I technicians for training. Many laboratories may be glad to send an assistant to acquire this experience and thereby contribute to the possibility of advancing a service of urgent national and individual importance.

Any correspondence should be addressed to Dr. H. A. Davidson, F.P.A. Laboratory, 33 Wimpole Street, London, W.1.—I am, etc.,

ALECK BOURNE,
Chairman, Sub-fertility Committee,
Family Planning Association.

Vitamin Deficiency after Oral Penicillin

SIR,—The article in your issue of Oct. 26, p. 611, dealing with nicotinamide deficiency after oral penicillin interested me very much. Some time ago I was talking to a distinguished pathologist who made light of my suggestion that the eating of mouldy bread, often inevitable in prison camps, could be in any way harmful. The article now published would suggest that moulds may indirectly lead to vitamin deficiencies, apart from any direct poisonous action they may develop. It would be interesting to investigate the matter among former prisoners of war, in whom deficiencies were possibly caused in this way.—I am, etc.,

Colchester.

G. C. PETHER.

Acute Enteritis in Subtropical Climates

SIR,—Sea mail to the Mediterranean still takes a matter of weeks and so I have only just read your number for Aug. 17 in which there was an article (p. 225) on "Acute Enteritis in Subtropical Climates" by Dr. Ian MacGregor. I am interested in the aetiology of this disease. It occurs frequently in the Mediterranean, particularly in personnel who have recently joined the station, being labelled "Malta Dog" or "Gypso Fummy."

I would like to add a few more observations. First, it responds readily to treatment with sulphaguanidine; secondly, there is usually a certain amount of malaise associated with it though rarely any pyrexia; and thirdly, there is quite often history of a meal ashore the previous day. Dr. MacGregor suggested that the disease might be due to a lowering of the resistance of the intestinal mucosa by a chill or by the invasion of an unknown virus or group of viruses rendering it vulnerable to the bacterial flora of the bowel. This may well be so, the activity of these organisms being inhibited by the sulphaguanidine. An alternative suggestion is that it may be caused by a hitherto unisolated sulphaguanidine-sensitive organism absorbed from the food. My second two observations suggest some infective element in the aetiology. I would be interested to hear of any other facts that would throw light on this subject.—I am, etc.,

H.M.S. Chequers

J. C. E. PESHALL,
Surgeon Lieutenant, R.N.V.R.

Antenatal Supervision

SIR,—It is very significant to see from Lieut.-Col. R. R. Willcox's paper entitled "Some American Ideas on Venereal Disease Control" (Nov. 30, p. 825) that in New York State every physician in attendance on a pregnant woman must have a blood test done on her for syphilis. As an American put it, "Syphilis is sure bad for babies."

For a considerable time in one's own practice I have taken 10 ml. blood from every expectant mother at her first examination whether she was a "booked" case or referred by a midwife for an antenatal check-up. This has been sufficient for a routine Wassermann, Kahn, G.C.F.T., group, Rh type, and Hb %. Thanks to the co-operation of the local authority and the regional blood transfusion laboratory the only cost in money is the stamps, and the time and trouble involved are negligible.

No one would like the practice employed in New York State—of being officially ordered to do something. Here we prefer

to rely on a professional conscience, guided by advice and practice from our betters. Time and bitter experience have decided that every suspected fracture should be x-rayed and every expectant mother's urine tested for albumin—and that without "regulations." But what is the position generally about routine blood tests for syphilis in expectant mothers? If it is not a rigid routine procedure, where lies the fault? Sinister hints come from our obstetric chiefs that in any future national maternity service only those holding higher obstetric qualifications will be allowed to conduct abnormal labour—worse, the general practitioner may be shut out entirely from all "organized" midwifery. And yet have we had any clear lead from the obstetricians that routine Wassermann and Kahn tests should be done on every pregnant woman? May one go further and ask if it be the regular practice in the great centres of obstetric training? It may just be one of those awkward coincidences which prove nothing, but in the past month I have seen three expectant mothers who have had their previous supervision elsewhere. The first had attended the antenatal department of a large and very efficient provincial non-teaching hospital, the second a municipal clinic run by a very proud Midland city, and the third a world-famous maternity hospital. Yet not one of these women had had any blood investigations, and one had not had her pelvis measured or her blood pressure taken. At least that is her story, and she ought to know.

This, Sir, is a serious and fundamental matter. To protect the unborn baby and to recognize inheritable disease at the earliest opportunity should be the first aim of any medical service. As a profession we are proverbially slow to take up new ideas, and we shall be slower unless our leaders give us a clear lead and do it themselves.—I am, etc.,

Oakham

GORDON PURDY.

Sterilization of Syringes

SIR,—With reference to the letter from Lieut.-Col. R. R. Willcox (Nov. 2, p. 667), I should like to hear some more of the evidence as to inadequacy of spirit sterilization in the reduction of post-arsphenamine jaundice when boiling of syringes after each injection was made compulsory in the Army. I was in charge of a 200-bed V.D. centre for 8 months and could note no diminution in the incidence of jaundice after this rule came in, nor could I note that it was any higher in another centre, where I subsequently worked for 3 months, in which the sterilization rule was not observed. Admittedly many of my patients had had odd injections elsewhere, as we had many out-patients, but there were quite enough wholly treated at the centre to give a definite impression. Jaundice occurred generally during the second "course" and selectively after the third or fourth injection. This is difficult to square with theories of infection. It is also hard to see how a syringe used to inject acriflavine intravenously could transmit living virus (Hughes, Nov. 9, p. 685), or why an injection of penicillin would be more likely to contaminate a syringe than one of T.A.B., tetanus toxoid, or any of the other routine injections.—I am, etc.,

England.

Ex-R.A.M.C.

Double Gastric Ulcer with Perforation and Haemorrhage

SIR,—The article by Mr. M. Kaye on Double Gastric Ulcer with Perforation and Haemorrhage (Nov. 9, p. 695) was of particular interest to me as I had had to deal with similar complications only a few days previously, and this additional case seems worth recording.

A man aged 62 was referred to the out-patients' department of the Lincoln County Hospital on Nov. 6 on account of epigastric pain soon after meals for six months. He also gave a history of vomiting a quantity of "black stuff" on several occasions in the previous week and stated that the motions had been quite black. On examination, he was thin and pale, there was epigastric tenderness, the stomach was dilated, and waves of peristalsis could be seen. Blood examination showed haemoglobin 52%, colour index 1.1, R.B.Cs. 2,440,000 per c.mm. Next morning at 11 a.m. he complained of sudden onset of severe pain in the upper abdomen. When seen again, he was pale and shocked, the pulse was almost imperceptible, and the abdomen was rigid and tender. Morphine was given, a Ryle's tube was passed, and drip-blood transfusion commenced. His condition improved, and the abdomen was opened

about 4 p.m. under cyclopropane and local anaesthesia administered by Dr. Clutton-Brock. A quantity of free gastric contents was found due to perforation of a pre-pyloric ulcer on the anterior aspect of the stomach. There was gross induration and numerous adhesions were present. A two-thirds partial gastrectomy was performed and completed by an anti-colic anastomosis with a Hoffmeister's valve. The specimen showed a second ulcer on the posterior wall eroding the pancreas, which almost certainly accounted for the haemorrhage, the ulcers being of the "kissing" type. The patient was remarkably well on the following day, and has made a straightforward recovery; he is now (Nov. 20) getting up and about. Sections show no evidence of malignancy.

We were fortunate in this case in that the haemorrhage came on before the perforation and was not very severe. In view of his poor condition the operation seemed rather a hazardous undertaking, but one felt that gastrectomy was clearly indicated as only by this means could one deal effectively with the three complicating factors of perforation, haemorrhage, and pyloric obstruction—I am, etc.,

Lincoln.

G. A. BAGOT WALTERS.

Dental Anaesthesia after Coronary Thrombosis

SIR,—I feel I must join issue with your correspondent answering the question under the above heading (Nov. 30, p. 843). Patients who have "recovered" from (I should prefer to say have improved after) coronary thrombosis are among the gravest risks which the anaesthetist is called upon to face. A myocardium which consists to a greater or less but always a serious degree of fibrous tissue replacing the normal muscle, and which must perforce be served by narrowing and increasingly inefficient coronary vessels resulting in inadequate oxygenation, can never be anything like a "normal" risk. Nitrous oxide is a weak anaesthetic which entails a reduction in oxygen supply well below the atmospheric 20% to be effective. To administer this atmosphere deficient in oxygen to a myocardium already likely to be anoxic is to court swift and sudden disaster.

I would suggest two alternative techniques: (1) Thiopentone administered in the operating theatre (where all necessary facilities for resuscitation are conveniently at hand) with the patient sitting as upright as possible on the table. This guards against the inhalation of blood which might set up a laryngeal spasm, serious in its anoxic potentialities. Further, to guard against this complication the dental surgeon should be constrained to extract a few teeth at a time and to guard carefully the haemorrhage with swabs. After the operation the patient should be laid down and rapidly turned on to his side with the head low. He should remain lying down for some hours. (2) Cyclopropane anaesthesia induced direct and taken slowly to the beginning of the third plane. The patient should be sat well up for this and the same precautions observed by the dentist as before. The teeth can be extracted during the recovery period on the lines of the old-fashioned "straight gas." Cyclopropane has the great advantage that oxygen percentage can always be maintained above 20%.

The conduct of these cases is not a fair responsibility for the non-specialist; but if this is inevitable, I would suggest gas-oxygen with not less than 25% oxygen, supplemented with trichlorethylene through the wick vaporizer supplied with all the more recent gas machines, and administered by nasal inhaler if possible in a properly equipped theatre.—I am, etc.,

London, W.1.

F. BARNETT MALLINSON.

Postgraduate Education

SIR,—The letters of Mr. John Stallworthy (Oct. 5, p. 510) and Dr. John H. Anderson (Nov. 23, p. 792) lead me to record my gratitude for the warm welcome which many Service doctors received from the members of the medical profession in Australia. As a medical officer of the British Pacific Fleet I was privileged to receive correspondence tuition which was the gift of the Postgraduate Committee in Medicine of the University of Sydney to the Royal Navy. This tuition was of an original and helpful type well adapted to the conditions of Service life. While visiting Melbourne I received a great deal of assistance from the Dean of the Faculty of Medicine, who provided facilities for study in the University. These are two examples of the friendship and assistance which many of us received wherever we visited in Australia.

I would like to express my appreciation of this hospitality which we received from senior medical colleagues in Australia. Doubtless many other medical officers experienced similar hospitality in this and other Dominions during the war, and hope that the return of peace will not lead to a cessation of this friendly postgraduate training within the British Commonwealth.—I am, etc.,

Glasgow.

J. MACLEAN SMITH

Legal and Medical Insanity

SIR,—I am grateful to Dr. C. J. de Vere Shortt for his observations (Nov. 23, p. 794) on my letter (Oct. 12, p. 555). He states: "There is, to the informed, a great difference between the two forms of insanity" [i.e., medical and legal]. The trouble is, however, that there is usually only one person being defended.—I am, etc.,

Westcliff-on-Sea.

JOHN A. MCCLUSKIE.

Demobilized Specialists

SIR,—I agree very largely with Dr. J. S. McKenzie Pollock's views (Nov. 23, p. 792) on demobilized specialists. It is pertinent to ask what makes a specialist. Is it rank, qualification, or experience?

At best many ex-R.A.M.C. officers are no better than "specialoids." By all means let these be given help to pursue their specialty, but not to the exclusion of their less favoured fellow-officers who are once again in civilian practice and are as keen to serve as they were in the Forces.—I am, etc.,

Edinburgh.

A. WYNN WILLIAMS

Recruitment to I.M.S.

SIR,—Your Educational Number, dated Sept. 14, in an article purporting to give information to prospective candidates for the public services, states (at p. 392) that R.A.M.C. officers have the opportunity to transfer to the I.M.S. This is incorrect for two reasons: (a) The I.M.S. ceased all recruitment to its ranks on the formation of the I.A.M.C. in 1942 and officers of the I.M.S. like myself are now seconded to the I.A.M.C. The I.M.S. therefore may be said to be dying a natural death, and when the last recorded officer dies or retires will itself die. (b) The policy of recruitment to the I.A.M.C. is to recruit only Indian domiciled officers, and so far as I know it is not open to Europeans.

The future of the European officers of the old I.M.S. is not the subject of this letter, and the above is written with the intention of correcting the false impression your article gives the reader. Official information on this subject is presumably available from the Director-General, I.M.S., G.H.Q., India.—I am, etc.,

Cambridge

C. W. A. SEARLE,
T/COL. I.M.S./I.A.M.C.

* * We are obliged to Col. Searle for pointing out the error. Recruitment of Europeans to the I.M.S. has ceased, though the Civil branch still exists. Full information may be obtained from the Secretary, Military Dept., India Office, Central Buildings, Matthew Parker Street, London, S.W.1.—ED., B.M.J.

Work of the Government Lymph Establishment

SIR,—I much regret if in my article "Work of the Government Lymph Establishment, July, 1898, to June, 1946," I may have given the impression that Dr. Blaxall and I were attached to the Government Lymph Establishment during the entire period from 1898 to 1946.

I retired from the directorship of the Government Lymph Establishment in 1930. Dr. Blaxall had died prior to that. Mr. Sutton was on the clerical staff, attaining the position of head clerk towards the end of the war.

From 1930 until his death in 1945 Lt.-Col. W. D. H. Stevenson was the director and Dr. G. G. Butler assistant director. The gigantic output of vaccine lymph was achieved by them, assisted by a very capable and loyal staff who never spared themselves in any way to procure the outstanding results.—I am, etc.,

Ryazab, West Malaya.

H. S. FREMLIN

Obituary

We regret to announce that Wing-Cmdr. THOMAS STANLEY RIPPON, O.B.E., M.S., R.A.F.(ret.), died on Oct. 4 at his home in London after a long illness. He was born at Warrington on Sept. 19, 1883, son of the Rev. Thomas Rippon. He studied medicine at Bristol and the London Hospital, and qualified M.R.C.S., L.R.C.P. in 1911. In the war of 1914-18 he held a commission in the R.A.M.C. for two years in France, and, having transferred to the R.A.F., served in India and Egypt after the armistice. In 1923, with the rank of squadron-leader, he joined the research staff at Northolt aerodrome. During further service overseas he was elected vice-president of the Mesopotamia Branch of the B.M.A., and after retirement from the R.A.F. he became a member of the Naval and Military Committee, and had a seat on the Council for four years. Rippon was for a time president of the Central Medical Board of the R.A.F. In more recent years he worked as assistant physician to the Tavistock Clinic and clinical assistant in the neurological out-patient department of the Royal Northern Hospital, Holloway, and at the Princess Beatrice Hospital, Earl's Court. He was the author of the section on aviation in the *British Encyclopaedia of Medical Practice*, and published papers on temperament and Service flying and on air-sickness.

Dr. RODERICK MARTIN FRASER, of Stornoway, Isle of Lewis, died at the Aberdeen Royal Infirmary on Oct. 8 following a major operation. Born in 1899, educated at his father's school in Stornoway and at the Nicolson Institute, he served with the Black Watch and was badly wounded in 1918. He took up his medical studies at Aberdeen University in 1919, and graduated M.B., Ch.B. in 1924. After a few years of assistantships in medical practices in the Midlands, he returned to his native town, where he became a popular and hard-worked practitioner. Many friends within the profession regret the passing of this hearty, able son of the Highlands, and in particular his fellow-students of Aberdeen University in the post-war years.

Dr. STEPHEN ANDREW CORNELIUS died suddenly on Oct. 23. Of Indian birth, Dr. Cornelius studied at Bombay University and took his B.Sc. in 1908. Subsequently he came to England and studied at University College Hospital, qualifying in 1915. After acting as house-physician at University College Hospital and as a clinical assistant at the Maudsley Hospital, he went to Swindon in 1918 and joined the staff of the G.W.R. Medical Fund Society. In 1921 he left for India, but returned to England five years later and became established in private practice in Swindon. He was honorary anaesthetist to the Swindon Victoria Hospital and a former chairman of the Swindon Division of the British Medical Association. By rare devotion to his fellow men Stephen Cornelius illuminated the profession to which he devoted his life. A man of wide culture and interests, he endeared himself to his many patients and friends by his unremitting labour, and by his manifold acts of kindness and generosity. In him were combined the best qualities of the family physician in the old tradition.

We regret to announce that Dr. SUTTON DUDLEY GILL died on Oct. 28 in his 91st year. The third son of Harry Gill, of Birmingham, he was born on June 21, 1856, and from King Edward's School he studied medicine at Queen's College, qualifying M.R.C.S., L.R.C.P. in 1892. Dr. Gill practised in West Bromwich throughout his long life and took a very active part in its public affairs. He was Mayor of West Bromwich in 1923, and alderman later; for many years he was the chairman of the Maternity and Child Welfare Committee, and in recent years was the "Father" of the town council. He leaves two sons, who are both members of the medical profession.

Dr. WILLIAM FRANKLIN O'REGAN died at Whitechurch, Cardiff, on Nov. 3, aged 63, after a painful illness of many months which he had borne with fortitude and no complaint. He was educated at the Christian Brothers' College, Cork, and took his medical course at Queen's College, Cork. While there he entered fully into the social and athletic activities of the College, was a member of all athletic committees, editor of the students' magazine, and a principal speaker in the debating society. He graduated as M.B., B.Ch., N.U.I. in 1912 and came to England as house-physician to the Salop Infirmary, Shrewsbury. He served in the 1914-18 war, most of the time in India, where he acted as lieutenant-colonel for a period. Returning, he took up practice at Lloyd Square, Islington, and was a foundation member of the Irish University Club in London. He began practice at Whitechurch twelve years ago. Of a

singularly retiring disposition, his courtesy, kindness, and charm of manner endeared him to all his patients, and strict adherence to the rules of his profession gained him the deep respect of his medical colleagues. His hobbies were music and literature. Owing to the illness of one partner and the absence on service of another during this war he was greatly overworked in a very large practice. He is survived by his wife; two daughters. His only son, Flying Officer Brian O'Regan was posted missing after a bombing raid to the Continent. Dr. O'Regan was a member of the B.M.A. and served on local executive committee and Branch Council in recent years.

Dr. JOHN GAWLER MURRAY, who died at Wokingham Nov. 13, was a good country practitioner and popular with patients. On qualifying at Edinburgh in 1897 he first settled in Scarborough, where his father had practised before him and held among other posts that of Admiralty Surgeon's Agent. This involved his going to sea to render assistance to many ships which had been mined by the Germans during the 1914-18 war. Later he joined the R.A.M.C., with the rank of major, and was in charge of the military hospital in Scarborough, where he had to deal with the casualties sustained during the bombardment of that city. After the war he moved to Blakesley, in Northamptonshire, where he set himself up a large practice. He retired to Wokingham early in 1939, and on the outbreak of war was soon in demand as a teacher of first-aid. Dr. Murray took a great interest in his work and had been an instructor at one of the civil defence schools. More recently he helped the local practitioners taking the place of men who were away on service, though he was by then over 75. In fact he worked up to the last and died practically in harness. He was married, and leaves a widow but no family. His passing is regretted by a large circle of friends both at Blakesley and at Wokingham.

Dr. W. R. CUMMING died at Bexley Heath on Nov. 15 at an early age of 52. A graduate of Glasgow, he took his M.A. in 1919 and the M.B., Ch.B. in 1923. He settled in Bexley Heath in 1929. During his seventeen years there he was an active member of the Dartford Division of the B.M.A. and was chairman in 1936-7. He was an honorary physician of the Bexley Cottage Hospital, in which he took a very great interest. A colleague writes: Always thorough in his work and sound in his judgment, Dr. Cumming was a man of upright character. These qualities made him well liked by his patients and friends and he was a fellow practitioner with whom it was a pleasure to associate. He will be sadly missed by all who knew him. He leaves a widow, a son, and two daughters.

Dr. SYDNEY DAVID SHEARE, who died in London on Nov. 1, qualified from Guy's Hospital in 1944, and after working pathological histology at St. Thomas's Hospital was for a time a voluntary assistant in the department of pathology in the British Postgraduate Medical School. "C.S." writes: The untimely death of Dr. Sydney Sheare is a sad loss. His courage and stoicism in the face of a long illness, of which he knew the result, will long be remembered by those who knew him well. In some ways he was a martyr to medicine as a doctor he proved to be an exceptional patient. Few have fought adversity with such determination and yet achieved success in their work. His warmth of character was equally only by his kindness and generosity, and his ability as a raconteur reflected a truly versatile personality. Deep sympathy is extended to his wife, Dr. Peggy Sheare, and his mother, in their immeasurable loss.

CHARLES WILLIAM DEAN, the doyen of the profession in Lancaster, died on Nov. 15, only a few days after his eighty-sixth birthday. He had been a member of the B.M.A. since 1886. He was born in Lancaster, and spent his whole life there, if one excepts the few years of his medical education in London and Edinburgh. Engaged for the most part in general practice, he yet found time and opportunity to train himself and to excel in general surgery. He became well known over a wide area as an operating surgeon, and enjoyed and deserved the esteem and confidence of his colleagues. He was the first surgeon in Lancaster to remove an appendix—over fifty years ago. In ophthalmic surgery, too, in which he was especially interested, he made a name for himself. From first to last he was connected, as house-surgeon and then as a member of the honorary surgical staff, with the Royal Lancaster Infirmary. In this hospital, which was very dear to his heart, he rendered invaluable service, and was popular with the committee and with the medical and nursing staff. Even during the recent war, when he was well over eighty, he worked in the ophthalmic department there as often as his health and strength would

'GENATOSAN' DERMATOLOGICAL CREAMS

Present medicaments for skin use in emulsified ointment bases. Many standard formulæ are available, and, in addition, Genatosan Prescription Service is prepared to compound physicians' own formulæ in any type of ointment base.

FORMULA:

% w/w Sulphathiazole - 5.0
"Genatosan" Base 95.0

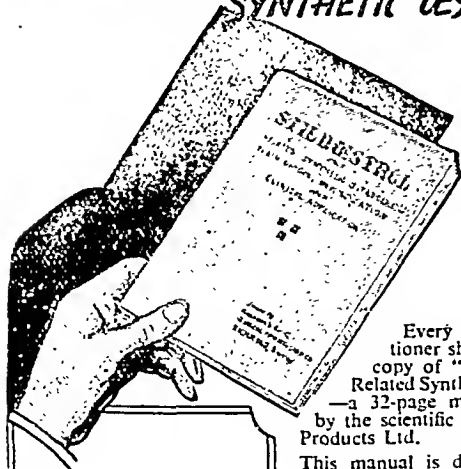

A card showing formulæ, and a descriptive brochure, are available on request from

STILBOESTROL and related SYNTHETIC OESTROGENS

"... a complete
guide to the
applications of
synthetic oestrogens
in clinical
practice."

Every medical practitioner should send for a copy of "Stilboestrol and Related Synthetic Oestrogens"—a 32-page manual compiled by the scientific staff of Clinical Products Ltd.

This manual is designed to give quick, easy access to available data on these important substances, and covers the significant works of leading investigators in the field of Stilboestrol research.

Menopax preparations—both the tablets and the anti-pruritic cream—are in constant and ever-increasing production to meet demand. Free medical samples and a copy of this book will be gladly forwarded on application to:—

Clinical Products Ltd.,
Richmond, Surrey.

Rational Antacid Therapy

APART from those cases due to actual organic disease, a treatment of the syndrome of symptoms known as indigestion generally resolves itself into an attempt to overcome hypersecretion of acid and to soothe the irritated or inflamed gastric mucosa.

That "Alocol" possesses intrinsic qualities which render it particularly valuable as a gastric sedative and antacid is now well established. Its freedom from the constipating effect of bismuth, the laxative action of magnesium salts and the gas-forming properties of sodium bicarbonate are especially noteworthy.

"Alocol" forms with the gastric contents a colloidal jelly which has the power of absorbing free hydrochloric acid. Its markedly soothing effect on the gastric mucosa promptly relieves pain and discomfort. It does not interfere with the normal process of digestion and is free from the danger of "alkalosis."

"Alocol" is available in Powder and Tablet form.

POWDER.—The normal dose is 1 gramme before and after meals.

TABLETS.—Each tablet contains: Alocol, 0.5 gms.; P. Sacch. Alb., 0.4 gms.; Cocoa Powder, 0.035 gms.; Excipient, q.s. The normal dose is 2 tablets before and after meals.

Complete chemical history of "Alocol," with convincing clinical reports and supply list, sent free to physicians on request.

NOW AVAILABLE—

'PALUDRINE'

The New Antimalarial

The production of 'Paludrine' in increasing quantities now enables demands for this important drug to be fulfilled without delay.

Extensive clinical investigations have established that 'Paludrine' is a highly efficient antimalarial with definite advantages over mepacrine and quinine.

- A single dose of 'Paludrine' (one or two tablets) controls the clinical symptoms of all forms of malaria and terminates the attack.
- 'Paludrine' is a true causal prophylactic in malignant tertian malaria and a partial causal prophylactic in benign tertian malaria.
- It produces radical cures in malignant tertian malaria, and a dose of one tablet once a week is sufficient to control the relapses of benign tertian malaria indefinitely.
- 'Paludrine' is a colourless drug and in normal dosage does not produce unpleasant symptoms of any kind.

'Paludrine' tablets of 0.1 gramme strength are issued in packings of 30, 100 and 1,000.

Available through your usual suppliers.

Literature will be forwarded on request.

omit. Charles Dean was neither a ready speaker nor a ready writer, though some of his occasional papers appeared in this journal and in the *Practitioner*. He never took part in public life, but he was keenly interested in music, and in his younger days was no mean performer on the French horn. His taste in literature was wide, and he had more than a superficial knowledge of heraldry. With a retentive memory, which time had not impaired, he had, as he used to say, "a mind stored with useless and irrelevant facts," which was perhaps one of the chief charms of his conversation. Quiet and reserved in manner, somewhat impulsive, always sympathetic, he was my colleague and friend for over forty years, and I can say only that the longer I knew him, and the better I became acquainted with him, the more I came to appreciate his character and to love his personality.—J. A. G.

Surg. Capt. ARTHUR GORDON VALPY FRENCH, R.N. ret., who died at Exmouth on Nov. 21, was born in London in 1883, son of the Rev. C. J. V. French, M.A., and was educated at Terborne School and St. Thomas's Hospital, qualifying (R.C.S., L.R.C.P.) in 1909. He was a medical officer at the R.N. Hospital, Haslar, 1911-14, and at the R.N. Hospital, Embroke Dock, 1919-22, after serving in H.M.S. *Carnarvon*, *Farshah Ney*, and *Vindex*. Later he was fleet medical officer of the Home Fleet, and then in charge of the R.N. Hospital, Malta. On relinquishing his commission he was medical officer to Elders and Fyffe's Shipping Company and served on the staff of the Admiral Superintendent of contract-built ships.

Squad-Ldr. WILLIAM M. HONEYMAN, R.A.F.V.R., who died on Nov. 24, entered St. Andrew's University as first bursar and graduated B.Sc. in 1932, and M.B., Ch.B., with commendation, in 1935. After holding two house appointments, he was awarded a Commonwealth Fellowship and studied at Columbia University and at the Phipps psychiatric clinic in Baltimore. On his return from the U.S.A. he was admitted to the membership of the Royal College of Physicians and became Halley Stewart Research Fellow in the M.R.C. unit at Queen Square. In 1939 he joined the Volunteer Reserve of the R.A.F., and on mobilization was seconded for duty to the psychological department of Cambridge University. There he worked on problems of applied neurology and psychology in aviation medicine right up to the time of his tragically premature death.

Dr. D. Russell Davis writes:

When Honeyman came to the Psychological Laboratory of the University of Cambridge he began to apply his knowledge of neurology and neurophysiology to the problems of normal human activity, particularly, because of his war duties, to that of aircrew. With his high intelligence, keenness, and thoroughness, and his excellent training in the U.S.A. and in Dr. Carmichael's laboratory at the National Hospital, there was every expectation that in due course he would make important scientific contributions in this field. Unhappily, the extension and development of his researches were retarded and radically cut short. He chose as a special study the influence of "after-contraction" upon skilled movements, but during the war he performed all manner of experiments. Probably the nearest was a demonstration of the effects upon their skilled manipulation of offsetting aircraft controls from the middle line of the body, a matter of great theoretical interest as well as of practical importance. His first serious illness was four years ago, and it is certain that this and later illnesses were a source of grave anxiety to him, but very rarely did he show what a heavy burden he was bearing. Although naturally reserved, he was liked and respected by all with whom he came in contact, and he retained his pawky humour, much enjoyed by those who discerned it, even in his last illness.

HENRY ST. GEORGE BOSWELL, a direct lineal descendant of Dr. Johnson's Boswell, was educated at Clifton and the Universities of Aberdeen and Edinburgh. He qualified at Edinburgh in 1882 and then assisted Rutherford Morison at Hartlepool for a year or two before marrying Morison's sister. Later he practised at Saffron Walden, where he was on the staff of the local hospital. In 1900 he went back to the old family practice at Hartlepool and spent the remainder of his working life there, endearing himself to high and low alike and having a wide and intimate circle of youthful friends. He was physician to the Hartlepool Hospital until 1925, when he retired and went to live in Whitby. Six years later he made St. Boswells-on-Tweed his home. In the art of medicine Dr. Boswell was skilled and understanding to an unusual degree, and as a friend and counsellor he helped many through life's trials and difficulties. He died on Nov. 17, and leaves two daughters and a son, Dr. Philip Rutherford Boswell.—E. W. O.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on Nov. 23 the following degrees were conferred:

D.M.—L. J. Russell (in absence).
B.M.—R. Ebsworth Snow, T. A. Madden.

UNIVERSITY OF CAMBRIDGE

Postgraduate Medical School

The governors of Addenbrooke's Hospital, Cambridge, have confirmed arrangements for the institution of a school of clinical research and postgraduate teaching, as set out in a recently issued report of the University General Board, with the University of Cambridge. It will ordinarily be known as the Medical School, and will comprise the Faculties of Medicine and Biology "B." So far the University has constituted the Departments of Experimental Medicine and Radiotherapeutics as part of the scheme; arrangements have also been made for more closely co-ordinating the Departments of Pathology and Biochemistry with the Hospital, with a view to improving the pathological services of Addenbrooke's and increasing the facilities for teaching and research. The academic activities of these departments will in future be amplified by the inclusion of clinical and pathological material from both the Hospital and the East Anglian region.

The Council of the Medical School will consist of the Regius Professor of Physic, who will be the chairman, the heads of departments in the Faculties of Medicine and Biology "B," and four members appointed respectively by the Boards of the Faculties of Biology "B" and Medicine, by the General Board, the General Committee of the Hospital, and the honorary staff of the Hospital. The staffs of the Departments of Pathology and Biochemistry will be increased so that they shall be sufficient to deal with the routine pathological, bacteriological, and biochemical work of Addenbrooke's Hospital. The General Board have therefore agreed to propose the establishment of three new posts, namely, University Morbid Anatomist and Histologist, University Bacteriologist, and University Biochemist. The holders, beside conducting the work arising from the Hospital, may be required to undertake lecturing and demonstrating; and though debarred from private practice they may attend private patients, any fees being paid into a fund administered by agreement between the University and the Hospital. The General Board recommend that the first-named post be filled by Mr. A. M. Barrett, the second by Mr. M. H. Gleeson White and the third by Dr. N. R. Lawrie.

When the postgraduate school is established the Senate of the Council will consider the possibility of setting up a pregraduate school of clinical teaching. It is hoped that Addenbrooke's will be designated a teaching hospital by the Minister of Health under the terms of the National Health Service Act, and in that event a Board of Governors would be appointed on which the University would be represented.

The forthcoming appointment of a university lecturer in pathology is announced in the *University Reporter*. The person appointed will be required to give instruction in bacteriology. Candidates should send their applications to the secretary of the Appointments Committee of the Faculty of Biology "B" at the Department of Pathology, Tennis Court Road, Cambridge, so as to reach him by Feb. 1, 1947. Candidates desiring further information about the duties and conditions of the post should write to Prof. H. R. Dean at the Department of Pathology.

An election to the Pinsent-Darwin studentship in mental pathology will be made in March, 1947. It is of the annual value of not less than £225 and is tenable for three years. The student must engage in original research into any problem having a bearing on mental defects, diseases, or disorders, but may carry on educational or other work concurrently. Applications should be sent before Feb. 23, to the secretary, Pinsent-Darwin Studentship, Psychological Laboratory, Cambridge. Applicants should state their age and qualifications and the general nature of the research they wish to undertake. No testimonials are required, but the names of not more than three referees should be given.

At a Congregation on Nov. 30 the degrees of M.B., B.Chir. were conferred by proxy on M. C. Joseph.

UNIVERSITY OF LONDON

The following candidates have been approved at the examination indicated:

POSTGRADUATE DIPLOMA IN PSYCHOLOGICAL MEDICINE.—J. F. Donovan and A. S. Ellis (with Mental Diseases Psychiatry) in Part B. Part A: M. R. Cliffe, Margaret T. Collins, D. D. Hoare, A. Karnat, T. McLardy, A. B. I. Platt, C. F. Ryecraft, A. Shapiro, K. R. Stallworthy.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The President of the College received on Dec. 2 a letter informing him that Le Comité de l'Association Française de Chirurgie "a décidé de faire don au fonds pour la reconstruction du Royal College of Surgeons of England d'une somme de 50,000 francs." This gift has been received with most grateful appreciation by the President and Council and will give great pleasure to all the Fellows and Members of the College. The sympathy of their French colleagues and their generous and spontaneous help will be a further bond of union between the surgeons and people of the two countries.

At a meeting of the Council, held on Nov. 29, with Sir Alfred Webb-Johnson, Bt., President, in the chair, Sir Cecil Wakeley, Vice-President, was appointed Bradshaw Lecturer for 1947, and Dr. Frank H. Lahey (Boston, U.S.A.) was appointed to deliver the first Cecil Joll Memorial Lecture in September, 1947.

It was decided to publish a periodical from the College to contain news items and College lectures.

The terms of the Petition and draft Supplemental Charter were approved for submission to the Privy Council.

In regard to the National Health Service the Council passed the following resolution: The Council desires the Negotiating Committee to enter into discussions and negotiations with the Minister on the Regulations authorized by the National Health Service Act.

The Services

The President of the U.S.A. has bestowed the Legion of Merit, Degree of Commander, upon Surgeon Vice-Admiral Sir Sheldon F. Dudley, K.C.B., O.B.E., F.R.S., K.H.P., retired, for service as Medical Director-General of the Navy.

Col. K. S. Master, M.C., K.H.P., I.M.S., has been appointed Colonel Commandant of the I.A.M.C.

The following appointments and mentions in dispatches have been announced in recognition of gallant and distinguished services in the field:

O.B.E. (Military Division).—Licut.-Cols. (Temp.) G. T. M. Hayes, M.C., and P. W. Kent, I.A.M.C.

M.B.E. (Military Division).—Capt. J. I. Rice, R.A.M.C.

Mentioned in Dispatches.—Capt. C. D. Sanders, R.A.M.C.

Majors (Hon. Licut.-Cols.) R. J. C. Hamilton and H. B. Lee, and Major K. W. N. Palmer, R.A.M.C., have been awarded the Efficiency Decoration of the Territorial Army.

The Faculty of Medicine of the University of Oslo adopted in 1939 a scheme for the reorganization of the medical curriculum. The execution of this plan remained in abeyance during the war, and the Faculty of Medicine has now decided to appoint a committee representative of the main interests concerned to reconsider the problem. To aid this committee, the Norwegian Medical Society organized a series of debates at its headquarters in Oslo. As a preliminary to these debates, the views of several authorities were given publicity in the *Tidsskrift for Den Norske Lægeforening* of Nov. 15. In the first paper, the surgeon, Prof. Johan Holst, wrote:

"Like our British colleagues, we should put the development of personality and character as the most important objective of an academic education." More concrete proposals concerned the speeding up of education. The prospective doctor should enter school at the age of 6 instead of 7, and the University at the age of 17, and he should qualify at 23, having studied medicine for six years, of which the last year should have been spent as an intern in hospital. In another paper, Dr. Hans Jacob Ustvedt emphasized the relative shortage of teachers of medical students. At Harvard University there are more teachers than students (673 to 500), while in Sweden there is one teacher to every eight or nine students. Norway has only one teacher to every fifteen students. The first meeting on Nov. 20 was remarkably well attended, and the show of grey heads and bald heads indicated that interest in the problems under discussion was not confined to the younger generation. The first speaker, a medical student, was not alone in complaining of a system which puts a premium on cramming, but it seemed to be easier to denounce it than to find an effective cure for it. A suggestion made by several speakers was that there should be a return to the old system of apprenticeship to certain approved doctors already in practice. On the subject of textbooks Prof. Kreyberg was vehement in his warning against any one book being authorized to the exclusion of others "Let them be in any outlandish language whatsoever, but don't let us have the book which the student learns by heart as he crams it." Norway will shortly have a second university, at Bergen, and to a certain extent this will start with a clean sheet while the old university of Oslo may have more difficulty in making changes.

Medical Notes in Parliament

Milk Priorities

Dr. SANTO JEGGER opened, on Dec. 3, a debate on milk priorities. He said that on Oct. 29 the Minister of Food issued to the medical profession a statement that an excessive amount of milk was being consumed. Compared with the war period the consumption of milk had increased by 400,000 gallons, or 44%, which was inconsistent with the statistics of disease. The official explanation was that certification by the medical profession had become less strict, but in his opinion an increase in minor ailments had a great deal to do with the increase in the consumption of milk. The Minister had appealed to the profession to adopt a more strict and accurate certification of diseases which required priority milk. Most doctors took a great deal of trouble to provide examination and an honest decision on patients who needed priority in milk. Some doctors were not so conscientious. He himself had been present not long ago at a conversation between two doctors, one of whom said: "You give me a certificate giving me priority in milk and eggs, and I'll give you one." The exchange was carried out. A doctor with a wealthy patient did not like to refuse a request for a priority certificate. Dr. Jeger recalled a letter to the *British Medical Journal* which told how a patient had changed her doctor to obtain milk for her cat. He thought that the categories in the schedule setting out reasons for giving priority certificates were too vague. Anaemias, varieties of debility, and psychological or nervous troubles causing loss of weight should be included in it. "Dyspepsia" and "colitis" were vague descriptions. Industrial workers confined to bed should get priority milk in the first ten days of illness and during convalescence. He suggested that there should be a new category of three and a half pints a week instead of doctors having to choose between two and seven pints a week. Doctors should give statements of illness, but the decision on priority should be made in the food office instead of in the doctor's consulting-room. The certificate should be valid for more than one month.

Dr. SUMMERSKILL said the decisions on priority were made by the scientific advisers of the Ministry of Health in co-operation with the advisory committee of the Medical Research Council. The Ministry also took into account publications by people like Prof. Cruickshank. Pathological priority categories took about 4% of the total consumption of milk in this country. The Ministry realized there were loopholes in certification and had decided that a letter should be published in the medical press. It was difficult to get the neurotic and hypochondriac person off the seat in the consulting-room and the general practitioner, a very harassed man, knowing there was a loophole, might do as he was requested. These cases added up to a formidable total. She had not heard of cases of doctors swapping certificates, but she instanced the issue of a certificate for 52 weeks. Such a practice would lead to lax certification. The convalescent industrial worker was covered. So far as minor diseases included in 2a were concerned, there had been no increase in consumption. The question of records must be examined by the medical profession and by the Government. She, when practising, had always felt that the categories were too vague, but the Ministry had to give the doctors some latitude. If the doctors did not observe the warning in the medical press the Ministry's next step would be to revise the Schedule. It would then give special consideration to 2c. It would also look into the position of the old people. The suggested ration of three and a half pints would remove the difficult patient from the chair in the consulting-room. That seemed a little immoral, but these difficulties had to be faced. Gastric ulcers were difficult to deal with as the sufferer might look healthy and the grant of priority milk rouse comment. She did not think it a hardship that patients had to get certificates renewed every month. Lax certification might follow if all certificates were made valid for three months. It would not be practicable for a professional committee of medical men to decide the eligibility of patients for milk. The Ministry would have to leave the general practitioner to decide.

The Willesden Affair

Mr. BOYD-CARPENTER inquired on Dec. 5 what action Mr. Bevan was taking to prevent the breakdown in hospital services threatened as a result of the action of the Willesden Council in directing that all nurses at that hospital who do not join a trade union should be dismissed.

On the same day Mr. BYERS asked how Mr. Bevan proposed to make good the deficiencies of doctors, nurses, and other staff who refused to comply with the demand of local authorities that they should join a trade union on pain of dismissal.

Answering the two questions together, Mr. BEVAN announced that he was sending a circular to local authorities pointing out that their primary duty as health authorities was to maintain the efficiency and smooth running of their health services and to ensure the welfare of the patients for whom they were responsible. All other considerations must be regarded as secondary. He added that while he was anxious that doctors, nurses, and members of similar professions should join a trade union or appropriate professional association, this was a matter which should not be determined by unilateral action of local authorities. He hoped there would be no breakdown of health services.

Mr. BYERS asked whether the Minister's reply could be taken as an assurance that the Government deprecated the irresponsible action of local authorities at a time when the nursing and medical professions were so shortly staffed.

Mr. BEVAN replied that the answer he had given was sufficiently clear. He did not wish to exacerbate feelings and hoped there would not be a repetition of the incident.

Mr. W. J. BROWN said Mr. Bevan's answer would be received with immense satisfaction by everyone who had the welfare of the health services and of the trade unions at heart.

Mr. BYERS, on Dec. 5, also asked Mr. Isaacs whether, in view of the injustice now being caused to individual nurses, teachers, members of certain religious bodies and others, by the enforcement of the "closed shop," it was still the intention of His Majesty's Government to leave this matter to both sides of industry.

Mr. ISAACS said that in so far as the cases to which Mr. Byers referred resulted from unilateral action by individual employers, regarding trade union membership of their employees, such action, whatever form it took, was to be strongly deprecated and was likely to be detrimental to harmonious industrial relations. The Government's view, in general, was that questions regarding terms and conditions of employment should be a matter for settlement between the two sides of industry in accordance with the constitutional machinery of the industry. He was not prepared to say that the Government would set up an inquiry. As a Minister he was using his influence with the organizations concerned to avoid these regrettable incidents.

SCOTTISH HEALTH BILL

In the House of Commons on Tuesday, Dec. 10, Mr. JOSEPH WESTWOOD, Secretary of State for Scotland, moved the Second Reading of the National Health Service (Scotland) Bill.

Mr. Westwood said that despite the progress made as a result of previous legislation there remained a large mass of sickness and defects of various kinds as revealed by the records of medical inspection of school-children, sickness returns of the insured population, and other figures. The Committee on Scottish Health Services reported in 1936 that in Glasgow about 16% of school-children were found to have ailments that could not be classified as minor; in the course of a year over 20% of the insured population were incapacitated for work, and the average time lost among the insured population was more than ten days per annum. Of the men applying for enlistment in the Army 38% were rejected on medical grounds. The vital statistics of Scotland were disquietingly less favourable than those of England and Wales and several other European countries.

With all these facts before them the committee came to the conclusion that changes in the size and distribution of the population, in social and economic conditions, in the habits and outlook of the people, and in the actual causes of death and ill-health required a readjustment of health effort. The first essential, to avoid overlapping, to secure a full return for expenditure, to keep the services in line with changing circumstances, and to secure that emphasis was distributed according to the social value of the varied services, was to integrate the separate services into a national health policy designed to promote the fitness of the people.

General Practitioner Service

Mr. Westwood went on to say that many persons, especially women and children, did not in fact receive adequate and timely attention because those responsible could not afford to pay for the services of a private general practitioner. He quoted the medical officer of health for Dundee who had said: "One of the most important criticisms of the organization as it exists at present is that advice and treatment are not immediately accessible to every individual unless the payment of medical fees is a matter of little or no moment."

These and similar findings had led to the committee's conclusion that as part of a policy for the promotion of the health

of the people it was necessary to secure that so far as possible all members of the community should have available the services of a general medical practitioner. On grounds of administrative expediency as well as on grounds of national policy it had become imperative for the State to frame a policy to meet the needs of at least the dependants of insured persons, and others in similar economic circumstances, and to lay down the lines along which the medical services should develop.

The Bill which was now before the House was drafted and directed towards providing for Scots people a comprehensive health service. It placed for the first time on public authorities central and local, the responsibility for seeing to the provision of all facilities needed for the health of the whole population.

Aims of the New Service

In the first place, it was to be the statutory responsibility of some public authority to provide every necessary form of health care—the family doctor, the specialist, the hospital, rehabilitation and convalescence, dental treatment, the care of sight and hearing, including the provision of artificial aids, special priority services for expectant and nursing mothers, young children, and school-children, and so on. There was to be full provision not only for the treatment of illness but also for the prevention of illness and the promotion of health.

Secondly, the Service or any part of it would be available to every man, woman, and child in the country. Although part of the cost was to be met from insurance funds there would be no insurance qualifications, nor any other kind of test based upon means, residence, or anything else. The new Service was for all practical purposes to be free of charge. This did not mean that it would not be an expensive business to provide the Service, although less expensive than allowing ill-health to continue unchecked. But the cost would be met mainly from the national Exchequer, and partly also from local rates and insurance contributions.

Central responsibility for the new Service as a whole was to rest with the Secretary of State. By his side, to give him expert advice on all aspects of the Service, there was to be a Scottish Health Services Council, with members drawn from all relevant fields of experience. Standing committees of that Council would be set up in connexion with particular parts of the Service.

Regional Boards and Executive Councils

Responsibility for the hospital and allied services was to rest in future with the Secretary of State. For this purpose all existing hospitals, local authority and voluntary, were to be transferred to him. The administration of these services was to be entrusted to a specially created regional and local organization. Five Regional Hospital Boards would act as agents of the Secretary of State, undertaking the general administration of the services in their areas. In turn, to act as agents of the Regional Boards for the control and management of particular hospitals, Boards of Management were to be set up. On these regional boards and boards of management members with all appropriate kinds of experience and local interests would find a place.

For the general practitioner services, Executive Councils were to be established, drawn mainly from local authorities and from representative professional committees in each area. The doctors and dentists would be encouraged to work from health centres, staffed and equipped so as to enable them to carry out their work in the most effective way. Responsibility for providing these centres would, in Scotland, rest in the first place with the Secretary of State. In order to improve the distribution of doctors throughout the country there would be provision for debarring additional doctors from entering the Service in an area already adequately covered. The sale and purchase of medical practices coming within the new Service would be forbidden, and compensation would be paid. Remuneration, while mainly by way of capitation payments, would include a basic salary element, which could be adjusted in accordance with the different needs of particular areas.

For a considerable range of local services, responsibility would rest as at present with the major local authorities, the county councils, and the town councils of the large burghs. In addition to their present maternity and child welfare duties, authorities would have a new duty to secure the provision of a home nursing service, and wide powers to undertake preventive and after-care services, including the provision of domestic help needed on health grounds.

The decisions taken by the Government were taken in the light of a great mass of information about the views and suggestions of the various interests concerned.

There were points of difference between the proposals in the Scottish Bill and those now embodied in the English Act. Conditions in Scotland were different in many important respects from conditions south of the Border. It was necessary.

therefore, to adjust the application of general principles to suit Scotland's particular circumstances and needs.

Health Centres

As regards the general practitioner division of the Service, the only important difference concerns health centres. In Scotland where conditions in different local authority areas vary widely, and the country as a whole is not an unmanageable unit, the early steps in health centre development should be undertaken directly by the Secretary of State. While the Bill enables the Secretary of State's functions in relation to health centres to be delegated to local authorities, he did not intend to exercise that power in the early and experimental years of the Service. The family practitioner's contract, in the health centres, as outside, will be with the Executive Council.

Basic Salary

Although payment by capitation fees should represent the larger part of the doctor's remuneration, there should also be an element of basic salary. This was a method of adjusting remuneration to varying conditions in different parts of the country. Basic salaries by another name had for the last 30 years been an essential feature of the Highlands and Islands Medical Service. It was, too, a means of reducing competition between doctors for patients. Sale and purchase of medical practices coming within the new Service in Scotland would be prohibited. Doctors who suffered loss in consequence of this prohibition would have their share of the £66,000,000 compensation.

In the new Service the family doctor would be able to call in a specialist whenever his opinion was required. The specialist service must be based on the hospitals and would be the responsibility of the hospital boards, but they would make arrangements with the Executive Council to ensure the close association of the specialist and the general practitioner.

Hospital Organization

While everyone accepted the need for a regional hospital system, it was not equally appreciated that no system of this kind was possible so long as there were two different forms of hospital administration and ownership. In Scotland the voluntary hospitals had always had a very prominent place. Their costs in all directions had greatly increased and were still increasing. With any form of National Health Service it would only be right that they should be paid for their treatment of patients who took part in that Service. The payments for service to the State would bulk increasingly large in the revenue of the voluntary hospitals. The State could not go on handing over these large sums of money without having control. In Scotland there were about 250 hospitals belonging to the 55 local authorities and about another 220 voluntary hospitals, practically every one of which had a separate governing body. With this multiplicity of authorities you get overlapping, unnecessary competition, and gaps in the hospital service. The Hospital Surveyors spoke in terms of comprehensive units—large infectious diseases hospitals instead of small ones, the amalgamation of special hospitals for eyes, ears, nose, and throat, or cancer with the general hospitals. There was no possible chance of securing all these developments so long as the general hospital was a voluntary one and infectious diseases were the responsibility of a local authority. To an increasing extent we had to provide services which demand wide areas of up to half a million or a million people. The orthopaedic service was an example. A proper cancer service and the new branches of surgery like plastic and brain surgery needed an organization covering a million or perhaps even two million people.

These proposals were, so he thought, generally acceptable to those who have to work in the hospitals and even to some of the local authority and voluntary hospital people. We should have the same doctors and nurses, the same independent medical schools, many, perhaps, of the same people on the Regional Boards and Boards of Management, the same endowments would be available, even more than they were to-day, for new developments and for research. The maximum of independence and responsibility would be left with the Boards of Management.

Whereas the English Act puts the responsibility for the ambulance service on the local health authorities the Scottish Bill puts it on the Secretary of State. Although the number of hospital beds in Scotland was only about one-tenth of the total for the U.K., Scotland was training about a third of the medical students. Therefore the teaching hospitals bulked very large in the hospital service.

A full debate followed and will be reported in our next issue.

Medical News

Abstracts of World Medicine and Abstracts of World Surgery, Obstetrics and Gynaecology will make their first appearance in January, 1947. These two new journals are being published monthly by the British Medical Association, the first at an annual subscription of 3 guineas and the second at 2 guineas. Applications for subscription should be sent to: The Publishing Manager, *British Medical Journal*, B.M.A. House, Tavistock Square, London, W.C.1.

The Medical Section of the British Psychological Society will hold an open meeting in the House of the Royal Society of Medicine on Wednesday, Dec. 18, at 8 p.m. The meeting will be devoted to a discussion on "The implications of the National Health Service Act for all professional workers in the field of mental health."

The Thomas Vicary Lecture on "Naval Medicine in the Ages of Elizabeth and James" will be delivered before the Royal College of Surgeons of England (Lincoln's Inn Fields, W.C.) by Dr. E. Ashworth Underwood on Thursday, Dec. 19, at 5 p.m.

The Association of Anaesthetists of Great Britain and Ireland (45, Lincoln's Inn Fields, W.C. Tel.: Chancery 6965) has arranged a dinner-dance, to be held at the Dorchester Hotel on Saturday, Dec. 21, at 7.30 p.m., in connexion with the centenary celebrations in London of the first administration of ether in Great Britain.

On Saturday, December 14, at 2.30 p.m., Sir Wilson Jameson will open a new rehabilitation and occupational therapy centre in the Bromley and District Hospital.

On January 1 the National Vaccine and Serum Institute of China (National Epidemic Prevention Bureau) will open its new biological laboratories. This marks the return of the Institute from wartime headquarters in Kunming to its original home, Temple of Heaven, Peking. A scientific session will follow the opening ceremony.

The American Group Therapy Association will hold its annual meeting at New York City in January, 1947. The programme will include sessions on group therapy in private practice, the parallel treatment of a group of pre-school children with a group of their mothers, and research in group therapy.

On Nov. 27 Mr. George Isaacs (Minister of Labour and National Service) inaugurated at Bridgend the first "remploy" factory established for the employment of the severely disabled who are registered under the Disabled Persons (Employment) Act, 1944, as unable at any time, or for any prolonged period, to undertake employment or to engage in work on their own account otherwise than under "special conditions." It is anticipated that a total of eight such factories will be operating by next April, and a further forty in the ensuing twelve months, and special provision is contemplated for the tuberculous and the epileptics.

Tributes to the memory of Dr. Harold Mason Leete, medical superintendent of the Hull City Hospital and Sanatorium at Cottingham and the Evan Fraser Hospital, were paid when an inscribed plaque was unveiled at the City Hospital. The plaque, provided by the staff, commemorates Dr. Leete's service as medical superintendent from July, 1930, until his death on Feb. 15, 1945. Dr. Nicholas Gebbie, M.O.H. for Hull, presided at the ceremony.

The Ministries of Health and Food advise the public not to eat pork, pork sausage-meat, ham, or any pork product unless it has been thoroughly cooked. In some districts it is customary to eat sausage-meat raw, spread on bread like a meat paste. This is a dangerous practice. The statement issued jointly by the two Ministries continues: "Illness may also arise from eating pork or pork products which have been insufficiently cooked. If pork, pork sausages, and other pork products, including ham not bought already cooked, are thoroughly cooked, there should be no risk."

Dr. Carl Gentz, medical director of the Stockholm Corporation Tuberculosis Bureau, and two of its staff, Mr. Martin Korsner and Mr. Widlund, have arrived in this country to spend a fortnight studying British arrangements for the rehabilitation and aftercare of tuberculosis patients. Their programme, arranged by the British Council, includes visits to the Papworth Settlement, the British Legion's Preston Hall Settlement, the Egham Rehabilitation Centre, Farnborough County Hospital, and workshops, and discussions with experts.

Dr. Abdul Azim Bey, director of the Bilharzia Destruction Section of the Egyptian Ministry of Public Health, is visiting this country for a fortnight on his way back to Egypt from the United States. The British Council has arranged for him to visit institutions and meet experts concerned with tropical medicine in London and in Liverpool. He is one of the leading younger medical research workers in Egypt, and his work has been of special value to the Sudan Medical Service.

The Ministry of Food announces two improvements in the products distributed under the Welfare Foods Service. Potassium diode has been added to Vitamin A and D tablets for expectant mothers. This addition has been made on the recommendation of the Standing Committee on Medical and Nutritional Problems and the Goitre Subcommittee of the Medical Research Council. Each tablet will contain 0.13 mg. potassium iodide in addition to 4,000 U. Vitamin A, 800 I.U. Vitamin D, and 250 mg. B.P. calcium phosphate. Ministry of Food cod-liver oil has now been "cold cured," thus improving the appearance of the oil and removing the tendency for clouding in cold weather. Supplies of these improved products are now being manufactured and will shortly reach the public.

The annual report of the Bristol Hospitals Fund for 1945 has been published. The cover indicates that this Fund has raised 333,188 for voluntary hospitals and ancillary hospital services in its 7 years of its existence—a striking tribute to the value of contributory schemes. A letter from the chairman accompanies the report, and emphasizes the need for the continuance of voluntary contributions and for voluntary effort after the implementation of the National Health Service Act, which cannot happen until 1948 at the earliest. The report states that the new Hospitals Provident Fund, mainly intended for those who require assistance in connexion with the heavy expenses attached to maintenance and treatment in hospital or nursing home private or semi-private beds, was an immediate success.

The offices of the National Council for the Unmarried Mother and Her Child are now at 87, Tottenham Court Road, London, W.1. Tels.: General, Museum 2969; Case Department, Museum 3780.)

Mr. Hugh P. Laird has taken over the secretaryship of the London Hospital Medical College on the retirement of Mr. E. J. Burdon.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* the chief feature of the returns was an increase of 1,046 in the notifications of measles. The other large changes were rises in the incidence of scarlet fever 109 and of whooping-cough 77.

The increase in cases of measles was mainly contributed by the northern counties: Lancashire 413, Northumberland 152, Yorkshire West Riding 106, and Durham 72; the largest decline was Buckinghamshire 66. The largest increase in the notifications of scarlet fever was Lancashire 46. The local trends of whooping-cough fluctuated, with an increase in Lancashire 36 and decreases in Yorkshire West Riding 35 and Warwickshire 33. The chief changes in the notifications of diphtheria were decreases in London 15 and Lancashire 13, and there was an increase of 12 in Staffordshire. There were 7 further cases of paratyphoid in the continuing outbreak in Sheffield C.B. London had 21 and Surrey 11 cases of dysentery.

In *Scotland* rises were reported in the notifications of scarlet fever 65, measles 38, acute primary pneumonia 31, and diphtheria 10. Cases of scarlet fever in Glasgow increased from 107 to 157. The largest local change in the incidence of diphtheria was in the City of Dundee, where the cases increased from 4 to 12.

In *Eire* an increased incidence was recorded for diphtheria 10 and diarrhoea and enteritis 20, while whooping-cough declined by 28 cases. Of the 61 cases of diarrhoea and enteritis 50 were notified in Dublin C.B. An outbreak of typhoid involving 11 persons was reported from the urban and rural districts of Ennis, Co. Clare.

Quarterly Returns for Scotland

The birth rate during the September quarter was 20.9 per 1,000, the largest rate for any third quarter since 1925. The infant mortality rate of 45 per 1,000 registered births was the lowest ever recorded for any quarter in Scotland and was 13 below the average of the five preceding third quarters. The still-birth rate was 30 per 1,000 total births. The maternal mortality rate of 1.7 per 1,000 live births was less than half the average of the preceding five third quarters and was much the lowest rate ever recorded for any quarter in Scotland. The general death rate was 10.8 per 1,000, the lowest since the third quarter of 1939. The death rate from all forms of tuberculosis was 70 per 100,000, and that from respiratory tuberculosis was 56; these rates were, respectively, 3 below and 2 above the average of the five preceding September quarters.

Week Ending November 30

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,383, whooping-cough 1,878, diphtheria 301, measles 6,005, acute pneumonia 745, cerebrospinal fever 47, dysentery 58, acute poliomyelitis 18, paratyphoid 19, typhoid 3.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Nov. 23

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1946					1945 (Corresponding Week)

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

It is still not possible to publish the return of births and deaths for Eire for the weeks ended Oct. 26, Nov. 2, 9, 16, and 23.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Attiology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS, if reprints are required, as proofs are not sent abroad.

ANY QUESTIONS?

Alkaline and Acid Ash Diets

Q.—*What are the alkaline and acid ash diets?*

A.—Alkaline and acid ash diets are not in general use to-day. The terms refer to diets composed of foods which are either alkaline or acid in reaction. Alkaline foods include milk, vegetables, fruits, beans, potatoes, carrots, beetroots, peas, and raisins. Among acid foods are meat and fish, eggs, bread, wheat-flour, oatmeal, rice, prunes, and plums. Neutral foods are said to be sugar, fresh butter, and fats.

An alkaline ash, or lacto-vegetarian, diet may be given in cases of renal failure; the benefits of this, however, are more likely to be due to its low protein content than to its reaction. Similarly, an acid ash diet may be ordered in diseases in which there is oedema due to depleted plasma proteins; in this instance the value lies in the high protein content of the diet and not in any particular reaction it may have.

Calcaneal Spur

Q.—*A man of 60 has painful heels. X-ray examination shows the presence of calcaneal spurs. Are the spurs the sole cause of the trouble, and what is the treatment?*

A.—Spurs on the under surface of the os calcis are usually caused by a plantar fasciitis—i.e., an inflammatory lesion of infective or toxic origin which may affect tendons, ligaments, or fascia close to their bony attachments. Probably as a result of the hyperaemia, the periosteum proliferates and a spur of bone is formed. This is most commonly seen on the under surface of the os calcis. An organism which commonly produced fasciitis and spurs in the old days was the gonococcus. Recurrent attacks of pain are due to recurrences of the inflammation, aggravated to some extent by the trauma of weight-bearing. Relief is often given by hollowing out the upper surface of the heel of the shoe and replacing it with a spongy rubber inset. Various forms of electrical treatment—e.g., ionization, short-wave diathermy, and so on, sometimes help. It is wise to make certain that the patient has no obvious focus of infection. Operation is rarely indicated unless the spur is so large that it can be palpated, or a callosity forms underneath it. If the operation is done in the acute stage it is often followed by an increased deposit of new bone. In the particular case quoted a thorough search for a possible source of sepsis appears strongly indicated.

Ulcerative Colitis

Q.—*A male patient, aged 26, has suffered from ulcerative colitis for about eight years. I would be grateful for any suggestions as to treatment.*

A.—The aetiology of ulcerative colitis is still uncertain. It has been suggested that it may be due to a specific enterococcus, to a chronic infection with *Sh. flexneri*, to a lack of some factor which is responsible for maintaining the health of the normal colon, or to a neurotic illness. It is probable that the condition should be regarded as a syndrome, different cases having a different aetiology. Every patient should have a careful sigmoidoscopic examination with, if possible, a barium

enema. After eight years there may be strictures of the colon or a potentially malignant polyposis.

Medical treatment should be tried first. If there is an acute flare-up the patient should be in bed. Diet must be highly nutritious and completely free from all roughage. There is no specific remedy and a trial may have to be given to many different ones. Sulphasuxidine retention enemata (2%) with full doses by mouth, supported by penicillin, may be successful in some cases, in others there may be symptomatic improvement only following control of the secondary invading organisms. Local treatment may consist of retention enemata of silver nitrate 0.5%, tannic acid (2 gr. to the ounce—0.13 g. to 28 ml.) or of bismuth subgallate (2 gr.—0.13 g.) in a suspension of mucilage. If diarrhoea is frequent and painful, relief may be obtained from a starch and opium enema. Recently some dramatic responses have been reported after the ingestion of raw pig's intestines. A dried extract is now available; it should be given in doses equivalent to 1/2 lb. (225 g.) of the raw material daily and must be continued for at least one month. Any anaemia should be dealt with by repeated transfusions of fresh blood; in the opinion of many this forms our best method of treatment. Liver extract has no particular value, but if the patient has existed for a long time on a restricted diet several injections of a crude preparation should be given.

Surgery is best kept until medical treatment has failed, but should not be delayed until the patient is moribund. The mortality for any operation in this condition is high—over 30%. A transverse colostomy or an ileostomy is the operation of choice, but in any case the artificial anus should be retained for at least a year, and may have to be kept indefinitely. For strictures or polyposis a colectomy may have to be advised.

Rh Factor and Blocking Test

Q.—*Please define Rh factor, rh, Hr, Rh-positive, and Rh-negative. What is the antigen block principle and how is Rh typing carried out?*

A.—The term "Rh factor" has been used with a variety of shades of meaning. In a general sense it signifies a whole complex system of blood-group antigens and antibodies; in the most restricted sense it means the antigen D, described below. The terms "rh factor" and "Hr factor" have little meaning in the light of the present theory of the Rh system; the rh factor may be equated with the antigen combination cde and the Hr factor with c.

The Rh system of antigens is now regarded as being due to the action of six genes: C, c, D, d, E, and e (disregarding some rare varieties, which, however, fit admirably into an extension of the scheme). Three loci, closely adjacent to one another on a single chromosome, are involved. One locus can be occupied by one of the allelomorphous genes C or c, another by D or d, and the third by E or e. Thus a single chromosome will carry three of these genes (e.g., CDe or cDE) and an individual, having received one such chromosome from each parent, may possess Rh genes of three, four, five, or six kinds. Owing to the closeness of the three loci, crossing over between them is extremely rare and an individual almost invariably passes on intact to each child one or other of the chromosomal combinations received from his or her parents. Each gene gives rise to a corresponding blood-group antigen called by the same letter as the gene. Each antigen is recognizable by means of a single agglutinin called anti-C, anti-c, etc. (except that no agglutinin for d has yet been described). Every person thus has from three to five recognizable red-cell Rh antigens.

There is general agreement upon the scheme described above but some disagreement as to which genotypes shall be called Rh-positive and which Rh-negative. For clinical purposes it is most desirable that all persons possessing the gene and antigen D should be called Rh-positive, and those lacking D Rh-negative. In a more restricted sense, however, only the common genotype cde/cde is regarded as Rh-negative; the rarer types lacking D, such as Cde/cde, must then be called Rh-positive.

Rh typing for clinical purposes is carried out by treating the red cells of the person to be typed with anti-D (common anti-Rh) serum in a small test-tube at 37°C. (98.4°F.) for two hours, and then examining the cells microscopically for agglutination. For a full Rh typing (which allows the geno-

type to be determined absolutely or with a high degree of probability), the cells are tested with each of the five sera already mentioned.

The blocking test depends upon the existence of two forms of anti-D, one which agglutinates and one, the incomplete or blocking antibody, which attaches itself to the antigen on the red cells without agglutinating them but prevents the agglutinating antibody from doing so. Cells known to contain D are incubated with the serum suspected together with a known agglutinating antibody. Failure to agglutinate indicates the presence of incomplete or blocking antibody.

Blockage of Eustachian Tube

Q.—I developed a partial blockage of the Eustachian tube over a year ago. Orthodox treatment has given no relief at all. The partial blockage appears to be at the pharyngeal end of the tube and is most marked on swallowing fluids or on yawning. Hearing is noticeably impaired on the affected side. Investigation has ruled out any serious pathological condition.

A.—The blockage at the pharyngeal opening of the Eustachian tube is probably due to inflammatory swelling of the lymphoid tissue normally found there in greater or lesser amount. Orthodox treatment having failed to relieve the condition, radiotherapy should be worthy of trial. This treatment has been extensively used in the U.S.A., particularly by Crowe, of Baltimore, whose paper will be found in the *Annals of Otorhinolaryngology* (1945, 50, 15). The intention is to irradiate sufficiently to destroy the lymphoid tissue without affecting the mucosa. Radium or radon are preferable to x rays because the effects are more easily localized. The radium or radon container, attached to a straight applicator, is passed along the floor of the nose so that it lies alongside the Eustachian opening. The time of application should be calculated by a radiotherapist, depending on the dose and screening.

Cocaine Solutions

Q.—Is there any simple method by which one could check the amount of cocaine in, say, a 3% solution made up by the local chemist? Sometimes it seems that such a solution is not as strong or as effective as it ought to be.

A.—There is no simple method which the ordinary general practitioner can use to determine the strength of a small amount of cocaine solution. If he is doubtful about a particular solution he should discuss the question with the city analyst or the county analyst. These officials exist (partly) to ensure that solutions of cocaine and of other things are correctly prepared, and they work through the machinery set up by the Food and Drugs Act. The probability that a solution of cocaine is incorrectly dispensed is very small indeed. Its preparation is a simple matter for a pharmacist, who receives a long training in dispensing.

Wilson's Disease

Q.—A boy of 16 died of Wilson's disease—hepato-lenticular degeneration. He had had a severe jaundice in the first fourteen days of life, bronchopneumonia at the age of 4, and glandular fever at the age of 8. What is the probable fate of the two other children in the family, a girl of 19 and a boy of 12?

A.—This case presents an unusual feature. Jaundice within a few days of birth is not a recognized symptom of Wilson's disease. It is, on the other hand, a symptom of haemorrhagic disease of the newborn in which jaundice may be associated with lesions in the corpus striatum, that is, in the same region as Wilson's disease, and these lesions may cause permanent symptoms of striatal disorder. Nothing is known about the causation of Wilson's disease except its familial character. The history in this case suggests two possibilities. (1) That this is not a case of Wilson's disease but of the late results of haemorrhagic disease of the newborn, or (2) that the two disorders, in some cases at any rate, may be nosologically identical. It would therefore be wise to have the blood of the mother and the two remaining children examined for the Rh factor and to discuss the case afresh with the pathologist. Assuming that the case is an example of Wilson's disease, not enough is known about its

causation to estimate the risks of its appearance in siblings, but it would be helpful to examine the cornea in the brother and sister for the Kayser-Fleischer ring, which would indicate the presence of the disorder. A negative finding, however, would not exclude the risk of its subsequent development. The abdomen should be examined for evidence of cirrhosis of the liver. It is doubtful if tests of liver function would be of value.

Mental Deficiency

Q.—Under the Mental Deficiency Acts can a ten-year-old mongolian idiot be taken out of the custody of the parents? The child has attended the village school for the past four years. Now the local education authority proposes to transfer the child to a special school and the parents are opposed to the suggested change.

A.—If a child is certified as a mental defective under the Mental Deficiency Acts of 1913 to 1927, the local authority have power, if in their judgment the circumstances justify the step, to over-ride the parents' wishes and send the child to a special school. The sole criterion is what is best in the interests of the child. Possibly the child was reasonably well suited to the infant class of the village school for the past four years but has now outgrown it. If the parents wrote to the General Secretary of the Provisional National Council for Mental Health, at 39, Queen Anne Street, W.1, they would doubtless receive helpful advice.

INCOME TAX

Car Transactions

F. G. bought a new car in July, 1946, for £581, selling the old car for £225. The written down value of the old car, after deducting the 1946-7 allowance, was £33.

* * The assessment for 1946-7 will not be affected. For 1947 F. G. will be entitled to an initial allowance of 20% of £581 = £116, and a wear and tear allowance of 25% of £581 = £145, £261 in all. Per contra he will have to bring in as chargeable, whether the above claim is made for the new car or not, the "balancing charge" *prima facie* of £225 - £33 = £192. This charge, however, should not exceed the total of the allowances received on the old car; thus, if its original cost to F. G. was, say, £200 and the total allowances have therefore been £200 - £33 = £167, that amount, and not £192, is the amount of the balancing charge.

Travelling Expenses

J. M. is taking up an appointment shortly at a hospital, the journey to which from the residence is "long and difficult by public transport, but quite short by car." What allowance can be claimed if a car is bought for the purpose costing, say, £500?

* * No allowance will apparently be due. The cost of travelling between one's residence and the place where the duties of an office or of employment are performed is not a deductible expense. J. M. is in the position of many thousands of suburban residents who cannot deduct the cost of their season tickets to London in calculating their income-tax liability.

Car Expenses

A1 is medical officer of health for a district council and assistant medical officer of health for a county council. He receives a car allowance of £28 per annum from the latter, but no allowance from the former council. He bought a car in May, 1943, for £65 and received £60 from an insurance company in respect of its loss in Dec., 1943. He then bought a car for £100, which he sold in April, 1946, for £240, replacing it by a car which cost £260. What allowances can be claimed for 1944-5 and 1945-6?

* * It is assumed that A1 can arrive at a reasonably close statement of his running costs, including insurance, licence, etc. The first car, which was disposed of before April, 1944, does not affect the allowances due for the subsequent years. As regards the second car he is entitled to a wear and tear allowance for 1944-5 of £22 and for 1945-6 of £18. On the other hand, if that car was sold on or after April 6, 1946, he will be liable to a "balancing charge," the maximum amount of which will be the total wear-and-tear allowances given in respect of that car—i.e., £22 + £18 = £40. Some restriction of the total of running costs plus wear-and-tear allowances (less of course the £28 received from the county council) may be due if the cars have been used for private purposes.

LETTERS, NOTES, ETC.

Hospital Repairs

Dr. LESLIE HARTLEY writes from Camberley: The Treasurer of St. Thomas's Hospital told us at the old students' dinner that there was a ward at the hospital in which the blitzed windows had not yet been replaced by glass in spite of continual applications for a licence. The result is that the patients are either in semi-darkness or have artificial light. I think Mr. Bevan, the Minister of Health, in association with Mr. Shinwell, the Minister of Fuel, should bring this to the notice of Mr. Bevan, the Minister of Housing, otherwise the public will have little faith that this dual personality will deliver the goods on April 1, 1948, when the new Health Service comes into being.

Midwife and Doctor: Conduct of Labour

Dr. RICHARD A. MANCLARK (Great Bookham) writes: Surely the correct thing for the midwife is to obey the doctor and mention to her supervisor about the doctor's lack of interest in using a mask. New C.M.B. rules might simplify this matter. The attitude of doctors who can apparently decide whether their nasal secretions are harmful or not to the patient without bacteriological help indicates the drastic changes necessary in our education and approach to the art and science of obstetrics.

Case of Clicking Ears

Dr. R. D. ALLISON (Preston) writes: Referring to the case of clicking ears recorded by Dr. Elliott Emanuel (Nov. 2, p. 652): the mentioned soft crackling noise audible to others I can produce at will—bilateral or unilateral, fast or slow. I was unaware that this phenomenon was considered abnormal.

Mr. CHARLES TAIT (Windsor) writes: The correspondence about clicking ears prompts me to mention my personal experience of this phenomenon. This differs from the cases which you have reported in that it is under voluntary control. I have since childhood been able to produce this sound at will, and occasionally spontaneously when swallowing; and this is loud enough to be heard by an observer if he applies his ear to mine. I imagine that this is brought about by the opening of the Eustachian tubes, as has been suggested by Dr. G. A. Moulden (Nov. 23, p. 796).

Car Sickness in Children

Dr. C. R. CROFT (Plymouth) writes: The expert who answers the question on car sickness in children (Nov. 30, p. 842) recommends glucose and glasses. I have no experience of the latter, but glucose, even when easily obtainable, was without particular merit. I venture to recommend the following methods. (1) For short journeys. Boredom, particularly as a reaction after excitement such as a party, is the most precipitating factor. Food has no influence except that a child finds it more satisfactory to discard a good bellyful than a mass of mucus. The following will relieve boredom and prevent sickness: (a) Well-chosen anecdote. This is difficult to sustain and may be relieved by (b) raucous song, or (c) a supply of any food which is strictly not to be eaten yet reasonably accessible. Efforts to chew an apple silently are very effective. (d) A cargo of contraband or loot, calling for a sharp look-out to be kept for policemen. It is pleasant to record that over a follow-up period of seven years no instance of gross juvenile delinquency has been attributed to this form of therapy. (2) For long journeys. Children should be prepared for bed at the usual hour. With the help of luggage and 2-3 cot mattresses a communal bed is prepared in the back of the car, and the children are bedded down there in the proper manner. A start is made when order has been reasonably established, and by 8 p.m. the children will be sleeping soundly, and the parents are free to dine in comfort, the car and contents being left in the hotel yard. On arrival at destination in the early hours the children are carried to bed and will wake up in excellent—if not too hearty—spirits next morning.

The R.N.V.R. Club and Welfare Fund

Lieut. The Hon. W. W. ASTOR, R.N.V.R. (chairman, R.N.V.R. Club) writes: During the war no fewer than 2,700 doctors held commissions in the R.N.V.R. They served with great distinction in all classes of ships and in all parts of the world. Many lost their lives. It may therefore interest members of the medical profession to know that the R.N.V.R. Officers' Commemoration Fund has been opened to commemorate in a practical way the part R.N.V.R. officers played in the war and, in particular, those who lost their lives. The Fund has two objects (1) to purchase and equip the new premises of the R.N.V.R. Club, and (2) to start an adequate welfare fund to help R.N.V.R. officers and their dependants who

may stand in need. The new club will have a memorial tablet, and relatives of officers who were killed may through this fund have officers' names inscribed on it. This club was started during the war, and has grown from nothing to an institution with 10,000 members, and it provides good and cheap meals, accommodation, and amenities, particularly for junior officers. But it must leave its wartime premises, and without help it cannot get into new premises. The administration of the welfare fund is closely integrated with that of King George's Fund for Sailors. We sincerely hope that many members of the medical profession, so many of whom served in the R.N.V.R., will give their support. The money is urgently needed. R.N.V.R. officers themselves have generously supported the fund, but most of them are young, and it is hoped that the outstanding part that they played in the war (when they formed 80% of the officer strength of the Navy) will commend this appeal favourably to their fellow countrymen. Cheques should be sent to Commodore Earl Howe, R.N.V.R. Club, 52, Pall Mall, London. S.W.1.

"The Miasm of Marasmus"

Lieut. M. I. BOSTOCK, R.A.M.C. (M.E.L.F.) writes: It is interesting to speculate whether the diarrhoea of a new type which is discussed in the annotation "The Miasm of Marasmus" (Oct. 5, p. 497) is in any way related to the acute benign gastro-enteritis one frequently sees in young troops in the Middle East—possibly imported into the U.K. by returning troops. During this summer I have been R.M.O. with two units in Egypt and Palestine with a large proportion of very young soldiers (mostly aged 20 or younger), and about 100-120 cases have passed through my hands. Most of these bore a striking similarity. Almost all started abruptly with pyrexia of 100-105° F. (37.8-40.6° C.) and severe frontal headache, frequently a relative bradycardia of under 100; and sometimes mild meningism and widely dilated pupils were seen. Simultaneously or a few hours later symptoms of acute gastro-enteritis appeared, usually but not always with more diarrhoea than vomiting and moderate abdominal colic. The diarrhoea is watery and profuse—mucus occasionally and blood seldom being seen (and then usually the case proves to be a true dysentery). The pyrexia usually abates after 36-48 hours, and the gastroenteritis responds rapidly to 24 hours' starvation and large doses of kaolin and opium and belladonna. The patient is usually on his feet again and feeling perfectly fit 5 or 6 days after the onset of symptoms. These symptoms are not unlike those of preformed enterotoxin food poisoning, but the incidence and epidemiology was much more suggestive of an infective agent—possibly fly-borne—and as those cases that were admitted to hospital rather than unit sick bay seldom if ever had pathogens isolated from their stools, it seemed possible that this condition was a form of virus infection. Cases seemed to occur relatively seldom among older troops or troops with more than a few months' service in the Middle East.

Recurrent Bee Stings

MISS ANN SHERWOOD (Henley) writes: I have just read the "Any Questions" on "Recurrent Bee Stings" (Sept. 28). I was stung a few weeks ago and I too had an experience in some respects similar to that of the farmer. I became flushed all over, arms, legs, body and face, and I had a slight palpitation. My eyes became inflamed and I soon broke out into a profuse perspiration. I became normal after about 15 minutes after I had rested, though I felt slightly shivery.

Correction

We regret that in the leading article "Research in Tropical Medicine," published in the *Journal* of Dec. 7 we erred in attributing to the Liverpool School of Tropical Medicine the discovery of "an entirely new range of chemical substances having therapeutic action on the malarial infection of birds." The credit for this work should have been given to the members of the Imperial Chemical Industries team in Manchester. The members of the Liverpool School made their contribution by applying the new drugs to the treatment of human malaria and the investigation of the pharmacology of these drugs in the human subject.

Disclaimer

Mr. W. GRANT WAUGH (Durham) writes: I shall be very grateful if you will be good enough to publish a disclaimer of the entirely unauthorized use of my name in connexion with the alleged "arthritis cure" in Sunday and daily papers recently. I can assure you that this was not only not authorized or connived at but was made in contravention of a direct promise given me by the papers concerned. Those who know me would, I think, agree that notoriety of this sort is extremely distasteful to me, while the lurid description of the treatment merely gives rise to unjustified hope of "cure" to a very large number of sufferers.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 14 1946

MEDICAL ETIQUETTE AND ETHICS*

BY

N. E. WATERFIELD, M.B., B.S., F.R.C.S.

What is the difference between etiquette and ethics? Medical etiquette might be defined as rules of procedure which govern conduct of members of the profession in their relationship one with another, while ethical rules deal rather with the relationship of members of the profession towards the individual members of the public and also with their responsibility towards the State. These rules when formulated take into consideration not only the immediate consequence of their application but also the ultimate results. A Canadian writer on this subject says it is as impossible to define ethics as it is to define pain, that we can write the rules of ethics but cannot say what ethics are. I think there is much truth in this statement, and although I have not given a definition of ethics I have stated what is the function of ethical rules. These rules are often slightly referred to by the public as medical etiquette, and, in its view, have been drawn up by doctors to protect their own vested interests without reference to the interest of the patients, who are often annoyed at the restrictions these rules sometimes place on the freedom of action of the individual patient or doctor.

Codes of rules regulating the conduct of members of the medical profession date back to the earliest times. It is stated that there was a treatise published in Babylon in 2700 B.C. which dealt with this subject. It defined the personal responsibility of the physician, and fixed various fees for different services and the penalties for neglected practice. Among the ancient Egyptians a physician might be sentenced to death when a patient under treatment died in a manner not recognized as natural by the authorities.

Hippocratic Oath

The Hippocratic Oath is well known to all of you. It still remains a most appropriate code of conduct, and although it dates from 460 B.C. the maxims it contains are quoted to-day; and I believe that in at least one university the Oath is actually administered to the newly graduated. It states that when the physician has doubts about the diagnosis or treatment of a case it is his duty to call in a consultant; that he should not advertise; that he should be reasonable in his charges and if necessary should forgo them altogether; that he should lead a pure and moral life; that he should pay due respect to his teachers; that he should not give poisons or sanction the giving of them; that he should not bring about abortion; that he should not divulge matters which should be kept secret; and that he should not be ostentatious in dress or bearing. You will see from this brief summary how sound was the advice given, and that little modification or addition is needed to-day.

Under the Romans in A.D. 138 there were regulations governing the number of physicians practising, and only those who passed certain tests of their qualifications and character were allowed to practise. In 1224 the Emperor Frederic prescribed a form of instruction for those wishing to practise medicine and regulated the fees a physician might charge. In the Middle Ages the religious orders were for the most part responsible for medical treatment and there were few, if any, independent practitioners.

* Presidential Address delivered at the annual meeting of the Surrey Branch of the B.M.A.

In 1794 Thomas Percival drew up a set of rules which is really a code of medical etiquette rather than a code of ethics. It was published with a view to composing the quarrels of his contemporaries on the hospital staff. It pointed out that there may be two conflicting points of view: one that of the idealist, who lays stress on the interest of humanity as a whole, and the other which stresses the interest of the individual. The code lays down guides as to how these interests can be brought into harmony. One point of topical interest in Percival's code, when the average age of the G.M.C. is so much under discussion, deals with the age at which practitioners should retire from active work. Percival says: "The period of the commencement of senescence, when it becomes incumbent on the physician to decline the offices of his profession, is not easy to ascertain: so nice a point may be left to the moral discretion of the individual. But in the ordinary course of nature bodily and mental vigour must be expected to decay progressively, though perhaps slowly, after the meridian of life is past. As time advances, therefore, a physician should from time to time scrutinize impartially the state of his faculties, that he may determine bona fide the precise degree in which he is qualified to execute the active and multifarious offices of his profession." This is very excellent advice, but I wonder, even if we carry out this scrutiny, how many of us are capable of coming to an impartial decision. Perhaps under the new Health Bill the decision will be made for us by regulations drawn up by the Minister, who, endowed with supreme wisdom, will decide at what age we must retire from practice.

B.M.A. Ethical Committee

The B.M.A. set up an Ethical Committee in 1902 for the guidance of practitioners in their relationship to one another, to their individual patients, and to the State. From that time on it has been responsible for deciding ethical issues according to the ethical standards formulated by the Central Ethical Committee, which, after having been approved by the A.R.M., become binding on members of the B.M.A. Fresh situations are constantly arising. Among those which have occupied the attention of the committee in recent years have been the relationship of medical men to medical auxiliaries and chiropractors, the relationship of industrial medical officers to their colleagues, the responsibility of a medical man who is financially interested in the running of a nursing home or clinic or who acts as a director in a company which deals in drugs or medical appliances, and, just recently, the part medical men may rightly play in connexion with voluntary organizations—the one under immediate consideration being the Marriage Guidance Council.

Confidence and Consent

I have attempted to give you a very short summary of some of the landmarks in the history of medical ethics, and propose to devote the rest of my time to some of the questions which are of more direct interest to those in practice. I think one of the hardest problems to decide is when and what to tell. You will remember the direction on this question given in the Hippocratic Oath: "Whatsoever, in my professional practice or not in connexion with it, I see or hear in the life of man which ought not to be spoken of abroad, I will not reveal as reckoning that all such should be kept secret." The golden rule, of course, is that the confidence of the patient should not be betrayed and that information which has been obtained by the

doctor in the doctor-patient relationship must not be divulged without the patient's consent, either given or implied.

Consent may be implied when the information is given at the request of the patient for certificates or reports in order that he may obtain certain benefits from either the State or any clubs to which he may belong, or in order that he may be excused duty. You will notice the way in which the N.H.I. certificate is worded: "I hereby certify that I examined you on the under-mentioned date." This was originally done with the idea that you were informing the patient himself of the condition found, and it was the patient's own responsibility what he did with the certificate. There is, however, no particular point in having the certificate in this form, and the more ordinary form, "I certify that I examined [name]," is equally suitable provided it is handed to the patient himself. If the patient is an employee, say, of the Post Office or of a firm and presents himself for examination in accordance with instructions received from his employers, his consent to the making of an examination and the forwarding of a report may be implied. The same may be assumed when a person presents himself for a life examination or for a report to enable him to obtain compensation for an accident. But if a patient is under treatment and his employer rings up to inquire about him, no information of any kind which could possibly be considered a breach of confidence should be given without the patient's knowledge and consent, and in some cases it might be advisable to get this consent in writing. For example, if a patient were found to be suffering from T.B. and you thought that the employer should be informed, you would be well advised to get not only oral but written permission. I will give you some of the problems dealing with this matter which have been put to the Ethical Committee in recent years.

When to Give Information

I. The question is occasionally asked whether the police should be informed in the case of a patient being treated for the result of attempted suicide. This is considered a case where professional secrecy should be maintained.

II. Frequently inquiries are received from the police in a case where a dead baby has been found, and all the doctors in the area are circulated as to whether they have, about such and such a date, attended a woman who might possibly be the mother. The advice given by the B.M.A. is that under these circumstances the doctor should not tell, the reason behind this answer being that if it became known that such information would be disclosed, medical advice would not be sought and a double tragedy might result.

In 1914 a conference was held with the Lord Chief Justice, who said that the authorities desired (a) that information should be given by medical men in attendance on a woman who is suffering from the effects of abortion brought about by artificial intervention, and (b) that the circumstances in which it was desired that this communication should be made were subject to the three following limitations: (1) That the medical man was of the opinion, from his own examination of the patient and/or from some communication that she may have made to him, that abortion had been attempted or had been procured by artificial intervention; (2) that he was of the opinion, from his own observation of and/or from a communication made to him by his patient, that such artificial intervention had been attempted by some third party other than the patient herself; and (3) that the medical man was of the opinion that his patient, due to such artificial intervention, was likely to die and that there was no hope of her ultimate recovery. Subsequent to the conference the matter was considered by the Council of the Association and the following resolutions were passed: (1) That the Council is of the opinion that a medical practitioner should not in any circumstances disclose voluntarily information which he has obtained from the patient in the exercise of his professional duties; (2) that the Council is advised that the State has no right to claim that an obligation rests upon a medical practitioner to disclose voluntarily information which he has obtained in the exercise of his professional duties.

It is of course known to all of you that when appearing as a witness in a court of law the doctor is bound to disclose

knowledge in his possession, unless he is prepared to go to prison for contempt of court if he refuses the judge's directions. The privilege of professional secrecy granted to clergy and lawyers is not extended to medical practitioners.

III. A doctor examining for an insurance company asked whether he should accede to the request of the insurance company for information as to how the candidate acquired the disease he was found to be suffering from. He was told that he should give the full nature of the disease but should avoid expressing an opinion as to how it was acquired.

IV. Another interesting case occurred recently in the divorce courts where the issue turned on whether one or other of the parties had contracted venereal disease. Both parties had agreed to the doctor's disclosing the information in his possession, and it was held that there was no reason why he should not have furnished a report.

V. In another case the M.O. of a trading company abroad was asked by the manager whether the illness from which an employee was suffering and which necessitated sick leave was due to alcoholic poisoning, since, if this were so, by the rules of the company, of which the employee was aware, he would not be entitled to a free passage. The reply given was that the certificate should state the true facts of the case.

VI. Advice has been sought whether the doctor should inform the employer in the case of a nursemaid whom the doctor was treating for lues venerea in an infectious form, the patient refusing permission for her employer to be informed. The doctor was told that, if every effort to obtain permission failed and the patient refused to give up her post until she was cured, he would be justified in informing the employer. You will have noticed that the Hippocratic Oath says that such things as ought not to be revealed shall be kept secret. This was considered one of the exceptional cases where information should be given without the patient's consent, and which did not come under the category of something that ought not to be revealed.

What to tell a patient when he is very seriously ill may be a very difficult question to decide, but it is obvious that if a patient demands to know what is your opinion of his case he has a right to know it. There is no doubt that the will to live is a powerful factor in helping the patient to sustain the fight, and any expression that he has little or no chance of getting better should be made most guardedly and in terms which should not remove entirely all hope of recovery, for every one of us must have in mind cases where the seemingly impossible has happened.

Advertising

You will remember that the Hippocratic Oath condemns advertising by members of the profession, but there are methods considered ethical by which the existence of a practitioner can be made known to the public. The first of these is the doctor's plate. This should be of reasonable size and not unduly conspicuous. Forty years or so ago it was quite common to see the words "Physician and Surgeon" and not infrequently "Accoucheur" added as well, and in some poorer districts, where a shop window formed the front of a doctor's waiting-room, it was not unusual for a notice to be displayed which said that teeth were carefully extracted. The more usual and perhaps more dignified custom is to have either the words Dr. So-and-So, or the doctor's name followed by his qualifications. There is no objection to the hours of attendance at a surgery being displayed in small lettering.

Many queries are put from time to time with regard to the plate. Is it permissible to display it at a house the doctor proposes to live in but is not actually occupying, or at a site where a new house is being built for the doctor's occupation? The answer to these queries is that it is not considered an ethical procedure to do so. It is also not permissible to put up a plate where messages are taken in but where no patients are actually seen. The doctor's red lamp has, I think, almost disappeared. Another question sometimes put by practitioners of a specialty is whether they are at liberty to announce their specialty on the door-plate, the plea usually put forward being that they are constantly troubled by people who think they are in general practice. The answer is that it is not done in this

country although it is a common practice on the Continent ; or the proper path to the specialist is via the general practitioner, and a notification on the door-plate might be considered in invitation to a direct approach.

Publications in the lay press should not be used as a form of advertisement. I may perhaps quote the paragraph in the *Handbook* of the B.M.A., which deals with this matter ; it reads :

"From time to time there are discussed in the lay papers topics which have relation both to medical science and policy and to the health and welfare of the public, and it may be legitimate or even advisable that medical practitioners who can speak with authority in the question at issue should contribute to such discussions. But practitioners who take this action ought to make it a condition of publication that laudatory editorial comments or headlines relating either to the contributor's professional status or experience shall not be permitted, that his address or photograph shall not be published, and that there shall be no unnecessary display of his medical qualifications and appointments. There is a special claim that practitioners of established position and authority shall observe these conditions, for their example must necessarily influence the action of their less recognized colleagues. Discussions in the lay press on disputed points of pathology or treatment should be avoided by practitioners: such issues find their appropriate opportunity in the professional societies and the medical journals."

Questions are sometimes asked whether it is permissible for a general practitioner to publish in the press change of address, return from a holiday, or the fact that he has taken a partner. The answer is that none of these announcements is considered suitable for insertion in the lay press, but that the desired information may quite properly be conveyed to the patients in a letter or by a notice displayed in the doctor's surgery. However, I would say that under the special circumstances of the war it was considered desirable to allow announcements of the return of practitioners to be inserted in the lay press by the Local Medical War Committee on their behalf. A similar privilege was asked for on behalf of specialists, but it was considered that the proper place for such announcements was in the medical journals. One other point I should like to make is that it is sometimes obligatory from a legal standpoint that the dissolution of a partnership should be announced publicly ; when this is so, no objection would be taken to an announcement in the press. One other form of publicity which depends on a statutory provision is the exhibition in the post-offices of a list of the practitioners in the area who are doing N.H.I. work.

When a practitioner is appointed as medical officer to an organized body which provides medical care and attention to its members, it is the duty and responsibility of the practitioner to see that there is no improper publicity and no canvassing for members which might contravene the warning notice of the G.M.C. It must be remembered that the public has not the same ethical standard as the profession, so that the practitioner is well advised to be very much on his guard. Another trap for the unwary is that provided by the enterprising newspaper reporter in search of news. A few harmless remarks with reference to an article the writer has contributed to a medical journal made to a reporter of the sensational press may involve the doctor in a very awkward situation. The question of a practitioner's taking part in local politics is a matter for his own decision, but I think it might be said that it is unwise for a practitioner to take part in activities in which strong feelings are likely to be stirred up.

Rules have been laid down for the guidance of specialists who enter a district with the intention of starting to practise their specialty there and who wish to convey this information to their colleagues. The methods by which it is considered ethical to effect this are: (1) By calling on practitioners already established in the area and giving a personal explanation of arrangements and plans; (2) by sending a sealed postal communication to those practitioners who may be expected to be interested, provided such a communication contains no laudatory allusion to himself or his work; (3) by communications on professional subjects presented to the local Division of the B.M.A. or other medical organizations; (4) by sending reprints of his published works to those practitioners who may be expected to be interested.

Canvassing and advertising have both been most severely condemned and called forth the well-known Warning Notice

of the G.M.C. The practices by a registered medical practitioner (a) of advertising, whether directly or indirectly, for the purpose of obtaining patients or promoting his own professional advantage; or, for any such purpose, of procuring or sanctioning or acquiescing in the publication of notices commending or directing attention to the practitioner's professional skill, knowledge, services, or qualifications, or depreciating those of others; or of being associated with or employed by those who procure or sanction such advertising or publication; or (b) of canvassing or employing any agent or canvasser for the purpose of obtaining patients, or of sanctioning or being associated with or employed by those who sanction such employment—are, in the opinion of the Council, contrary to the public interest and discreditable to the profession of medicine, and any registered practitioner who resorts to any such practice renders himself liable, on proof of the facts, to have his name erased from the *Medical Register*.

Consultation

As laid down in the Hippocratic Oath, it is the duty of a doctor when in doubt about the diagnosis or treatment of a case to call in a consultant; but, in addition to this, certain circumstances may arise when it is, to say the least, advisable that a second opinion should be sought and a second doctor share the responsibility with the attending practitioners: for example, when it may appear that the performance of some operation, or the pursuit of some line of treatment, involve considerable risk to the life of the patient or may result in some permanent disability; before any operation for terminating a pregnancy for therapeutic reasons is contemplated; in the case of a drug addict where it is necessary to continue the administration of the drug solely for the relief of the symptoms of addiction; and, lastly, when there is reason to suspect that the patient has been subjected to an illegal operation or is the victim of criminal poisoning. Ordinarily the choice of consultant is in the hands of the attending practitioner, but, should the patient express a desire to call in a particular consultant it is usually wise to accede to the request provided the choice is not an unsuitable one. Consultations are not the formal proceedings they were in the days of the frock-coat, top-hat, and gold-headed cane, the disappearance of which marked the end of an era.

With regard to the actual consultation: when this is carried out in the patient's house, after a preliminary talk in which the patient's doctor gives a history of the case and expresses his own opinion the practitioner precedes the consultant into the patient's room and introduces him. After an examination has been made the doctor follows the consultant out of the room and the consultation is held. Then the consultant gives his opinion to the patient or his representatives. If the practitioner is in disagreement with the view expressed by the consultant, he has the right to put his view before the patient, who should then be asked to make a choice as to which line of treatment he prefers to follow. Should the choice be on the side of the course recommended by the consultant, the practitioner, should he feel unable to co-operate, would be well advised to hand over the case to a colleague.

Sometimes patients are anxious to have what they call an entirely independent opinion. When this is so, it is regarded as ethically correct for a consultant to see the patient without a letter from his doctor, but it is his duty to try to persuade the patient to let him communicate with the patient's doctor. In any event the consultant should not do more than express his opinion of the case. He should not, under any circumstances, accept the patient for treatment. When the patient attends at the consultant's house without the practitioner being present, the consultant will of course communicate his findings to the patient's doctor in writing, and if a second visit is desirable it should be left to the patient's doctor to arrange it. Likewise if another specialist's opinion is considered necessary, the choice of who should be employed should be left to the patient's doctor, who would doubtless fall in with any suggestion the specialist might make.

Recently the Minister of Health sought to establish the position that in the case of a patient diagnosed as or suspected to be suffering from tuberculosis and referred to the divisional medical officer, the latter should have the right to refer the

patient direct to the tuberculosis medical officer. The B.M.A. has strongly contested this view, and a reply has been received from the Minister stating that in those cases where the opinion of a specialist was considered to be desirable for reasons other than to enable the examining medical officer to report whether or not an insured person is incapable of work, no steps would be taken for the specialist's examination before obtaining the consent of the insured person's own doctor. The Ministry is being pressed to agree that *all* references to specialists shall be made only after consultation with the insured person's doctor.

In the event of a patient's being admitted to a nursing home or the pay beds of a hospital under a specialist, he then of course has the right to call in whatever help he requires. The question is not infrequently raised of who has the right to choose the anaesthetist when an operation is to be performed. The answer is that it is the right of the surgeon, as also in the case of dental operations, when the choice belongs to the dentist; it being understood that in both instances the patient's doctor has the right to be present at the operation. The responsibility for the fee of the consultant and of the surgeon rests with the patient's doctor. It may be paid directly by the patient at the time of the consultation or operation or may be collected by the doctor and forwarded to the consultant. In the latter case any account sent to the patient should make perfectly clear how the total is made up. Dichotomy, or fee splitting, between the surgeon and the practitioner is a most serious offence.

I think the two situations which the public most complain about are that medical ethical rules, or etiquette as the public choose to call them, place some restrictions on obtaining independent opinion and treatment from whomever they like, and that they are not at liberty to change their doctor without certain formalities being observed. The first question I have already briefly dealt with when speaking about consultations. The rules governing the other situation are, shortly, that when a practitioner supersedes another in the conduct of a case he must satisfy himself that the other practitioner has been informed that his services are no longer required; and when a practitioner is requested to visit a patient and has reason to believe that another practitioner is in attendance, it is his duty to inform the patient that he cannot attend without the presence or consent of the practitioner actually in charge of the case. If the attending practitioner, after being warned, declines to meet the practitioner invited, and if the patient or his representatives persist in the request, knowing of this refusal, or if the attending practitioner retires from the case, then the practitioner is entitled to take over the care of the case.

In the case of a practitioner acting as medical inspector—for example, for an insurance company in a compensation case—it is his duty to inform the patient's doctor and invite him to be present at the examination, but should the latter fail to respond the medical inspector, with the consent of the patient, can proceed with the examination. No criticism should be made of the treatment adopted and if any modification in the line of treatment is in his opinion necessary he should personally or by letter discuss this with the attending practitioner.

Covering

This is another of the most serious of ethical offences. It means enabling an unqualified person to carry on medical treatment which he would not be able to do unless he had a qualified practitioner behind him who is willing to fulfil certain obligations or render such assistance as he may require to enable him to carry on his work. For example, an unregistered practitioner may run a nursing home and undertake the treatment of patients; but without the assistance of a registered practitioner willing to sign death certificates of any patient who might die while in the home it would be impossible for him to do so. Or an osteopath may carry out manipulations for which an anaesthetic may be required. Here again, without the help of a registered practitioner his activities would be very much curtailed.

A question is sometimes asked as to the responsibility of a doctor who employs an unqualified dispenser. The answer is that under no circumstances can the dispenser make up medicines which contain poisons in any shape or form, but

provided the person works under the close supervision of the doctor she is allowed to dispense other medicines. There is one situation which has recently arisen about which practitioners have to be very much on their guard. This arises from the position created by the enactment making it illegal for a person who is not qualified or registered as a midwife to attend for gain a confinement or during the lying-in period, and the doctor would be held guilty of an offence if he attended a case where such a person assisted him in any way with the nursing of the case.

It may have occurred to you that there are some problems which from time to time are under discussion by the public, such, for example, as euthanasia, contraception, and more recently artificial insemination, about which the medical profession as a body might have been expected to pronounce and formulate rules for the guidance of the profession, but it is generally accepted that these are large moral questions on which an individual member of the profession is at liberty, in the same way as any ordinary member of the public, to form his own opinion and to use his own judgment as to the attitude he shall take towards them. As an aside I should like to say a word on the practitioner's attitude towards the dying. There are two aphorisms which seem to help in defining this. The first is: Thou shalt not kill but need not strive officiously to keep alive; the other: There is no moral obligation to prolong the act of dying.

The title of this address is "Medical Etiquette and Ethics," but I have found in the course of preparing it that it has been very difficult to separate the two subjects, and many points of etiquette have been dealt with when an ethical point has been under discussion. There are, however, two points of etiquette which I should like to stress before finishing. First, the necessity of always sending a communication with the patient sent for consultation, either to the consultant or to a hospital, and of acknowledging any communication received after such a visit; and, secondly, I would mention the custom, which I am afraid is more neglected than it should be, of a practitioner newly entering a district calling on the practitioners living there.

CARE OF CHILDREN

A joint circular from the Home Secretary, the Minister of Health, and the Minister of Education has been sent to local authorities to draw their attention to certain comments and suggestions in the Report of the Care of Children Committee. The Report recognizes that difficulties in recruiting staff and finding suitable accommodation for the children exist. Nevertheless, such faults as lack of co-operation between different departments of the same authority and failure to treat the child "as an individual with his own rights and possessions . . ." also occur, and these do not require legislation for their correction. It is not only the child's physical needs that are important: an atmosphere of affection, security, and personal interest is equally so.

With the object of allowing certain men and women to call themselves Probationer Assistant Nurses until the end of 1948 instead of the end of 1947 as formerly, an amendment has been made to the Nurses (Scotland) No. 2 Regulations, 1945. The title "Probationer Assistant Nurse" is intended to be used only by men and women of 18 or over who are qualifying for admission to the Assistant Nurses' Roll by undergoing a period of whole-time experience—usually two years—in the nursing of the sick in hospitals under the supervision of trained nursing staff. Men and women who satisfy the requirements of the General Nursing Council may obtain admission to the Roll in this way until the end of 1948. To do so, however, they must enter a hospital on or before Jan. 1, 1947. Those who enter a hospital after that date in order to qualify as Enrolled Assistant Nurses will have to undergo systematic training in Assistant Nurse Training Schools and will have to sit for an examination.

The Wheatley Committee has recently announced salaries for Probationer and Enrolled Assistant Nurses.—*Women:* Annual resident salary: Probationer Assistant Nurses, first year £55; second year £65 (emoluments £75); Enrolled Assistant Nurses, £100 rising to £160 (emoluments £100). *Men:* Weekly non-resident salary: Probationer Assistant Nurses, 86s. rising to 98s.; Enrolled Assistant Nurses, 92s. rising to 112s.

THE WILLESSEN AFFAIR

Willesden Council have rescinded their notice to dismiss the doctors and nurses in their employment if they do not join trade union. All the notices have been withdrawn without exception. The General Purposes Committee of the Borough Council met on Dec. 4 and passed the following resolution:

In accordance with the public undertaking given at the Council meeting on Nov. 25 that the resolution relating to employment should not be administered in a harsh and doctrinaire manner, and membership of a trade union affiliated to the T.U.C. is not necessary for the purposes of the resolution, we recommend:

That trade union membership or membership of any association, corporation, college, or body of persons whose functions are for the time being recognized by the Council as including negotiation of rates of salaries or conditions of service of the members thereof be a condition of employment of all persons continuing in or entering service of the Council.

That the following be recognized by the Council: The British Medical Association, the Royal College of Nursing, the Royal British Nurses' Association, and the College of Midwives.

That all employees on whom notice to terminate their contract of service has been served because of failure to comply with the Council's resolution regarding trade union membership be informed of the above amendment to such resolution and be offered re-engagement as from the date of the termination of their previous contract of service on the terms and conditions of such previous contract, together with the conditions set out in the resolution of the Council of Sept. 24, 1946, as amended above.

It is understood that the Council, since passing the above resolution, have withdrawn all their demands and now no longer require their doctors and nurses to be members of any organization whatever, whether a trade union or a professional body. The position of these employees therefore reverts to what was before the unhealthy movement started.

Public outcry against what the *Times* called the Council's defensible doctrine has been widely ventilated in the Press. That it is reflected in Ministerial minds is evident from Mr. Herbert Morrison's remarks at a luncheon of the Institute of Incorporated Practitioners in Advertising on Dec. 5, when, referring to the shortage of nurses in hospitals, he added: "Why one or two local authorities should go messing about with this . . ." Applause drowned the rest of his sentence.

The Minister of Health was equally direct and condemnatory when opening University College Hospital's new nurses' home on Dec. 5. Saying that the foremost preoccupation of municipal and voluntary hospitals must be the welfare of the patients, and not any other preoccupation, be it political, professional, or trade union, Mr. Bevan referred to the Willesden affair and expressed the hope that local authorities throughout Great Britain would see that the spontaneous resentment against what had happened was a warning not to try to repeat it in their places.

This was followed on Dec. 6 by a circular from the Ministry of Health to all local authorities which contains the following paragraph:

The Minister wishes to make it clear to all local authorities that he considers that their primary duty as health authorities is to maintain the efficiency and smooth running of their health services, and to ensure the welfare of the patients for whom they are responsible. All other considerations must, in his view, be regarded as secondary, and he trusts that local authorities will follow this principle in their administration. While the Minister is anxious that doctors, nurses, and members of similar professions should join a trade union or appropriate professional association, he considers that this matter should not be determined by the unilateral action of local authorities.

As a correspondent points out in a letter on this page, the notices of dismissal were reported to be regarded as "premature" by certain Labour members of Willesden Council. It is to be hoped that the Ministerial censure to which they have been subjected will prevent any similar conceptions or misconceptions arising in the future.

Whether membership of the Monumental Masons' Union, as suggested by Dr. R. Dingwall Kennedy in a letter to the *cosman*, would be acceptable if such circumstances should arise again is an interesting speculation. It seems open to the criticism that, in the event of that union calling a strike, the rapidly accumulating dead would not even have the consolation of posterity's record.

Correspondence

The "Closed Shop"

SIR,—The implication in Dr. F. R. Ellis's letter (Nov. 23, p. 138) that the application of the principle of the "closed shop" interferes in some way with the liberty of the subject indicates a lack of knowledge of the practical details of trade unionism.

In fact, the application of the "closed shop" principle in industry is designed to prevent a recalcitrant minority from undermining the security and position which a majority group of workers have built up through trade union action. In this way the liberty of the subject is increased because the security of tenure of his job is increased, and he is no longer likely to have his wages whittled down—as he might have been but for the trade union. In addition, where wages and conditions in industry are the subject of negotiation between a trade union and the management, the negotiating machinery, from which all benefit, has to be paid for. It is not fair that a minority should escape this payment by claiming the right not to belong to a trade union.

As far as medical men employed by local authorities are concerned, membership of a trade union should surely be regarded as an advantage. Should there be any dispute between the employee and the employing authority the trade union can represent the member's interest. Medical men need some assistance of this sort. The B.M.A. is an excellent professional organization, but it cannot undertake trade union activity on behalf of its members in the way that the Confederation of Health Services Employees can do. I am a member of both organizations.

I readily admit that it is possible to conceive of circumstances when the application of the "closed shop" principle is not beneficial. Every principle can be abused. It is necessary to realize, however, that correctly applied the "closed shop" is one of the greatest assets to the trade union movement in ensuring the liberty and true freedom of the ordinary trade unionist.—I am, etc.,

London, S.E.24.

P. W. ROE

SIR,—It has been reported in a local paper that certain members of the Labour Willesden Council consider their dismissal notices to hospital staffs to be "premature."

The new Health Service is to be "controlled" by a series of committees to which a Labour Minister is to appoint every chairman, a certain number of members, and to "approve" the appointment of all other members. It is therefore fortunate that we have at Willesden a foretaste of the attitude which at least a portion of Labour members takes to the medical profession.

I am only sorry this did not happen sooner so that answers to the plebiscite could have been influenced by this warning and threat of possible things to come.—I am, etc.,

Birmingham.

WM. WATSON NEWTON

SIR,—Mr. Bevan has expressed great indignation at the action of the Willesden Council, but I feel that this indignation is partly due to the fact that their action was premature. In other words, they have let the cat out of the bag.—I am, etc.

Camberley.

LESLIE HARTLEY

Medical Unemployment

SIR,—Your correspondent "Another of the Unemployed" (Nov. 23, p. 138) has made sweeping statements which do not apply to all local authorities. I can give you as a contrast the details of a recent appointment of deputy medical officer of health in the county borough of Chester. The official application form requested details of war service, with ample space for such information. Five candidates were selected for interview, all of whom had served in the Forces during the recent war.—I am, etc.,

J. W. LOBBAN,
Medical Officer of Health
Chester County Borough

Association Notices

GROUP OF NON-PROFESSORIAL MEDICAL TEACHERS, LABORATORY AND RESEARCH WORKERS

A meeting of the Group of Non-Professorial Medical Teachers, Laboratory and Research Workers, to which all members of the Group are invited, will be held at B.M.A. House on Thursday, Jan. 2, 1947, at 2 p.m.

Members of the Group are invited to forward to the Secretary, B.M.A. House, Tavistock Square, London, W.C.1, suggestions or recommendations for consideration by the meeting.

(Sgd.) CHARLES HILL,

Secretary.

The Katherine Bishop Harman Prize

The Council of the B.M.A. is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1947. The purpose of the prize, which was founded in 1926, is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child-bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1947, but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question will be such proportion of the accumulated income as the Council shall determine. The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed, at B.M.A. House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1946.

Middlemore Prize

The Middlemore Prize consists of a cheque for £50 and an illuminated certificate, and was founded in 1880 by the late Richard Middlemore, F.R.C.S., of Birmingham, to be awarded for the best essay or work on any subject which the Council of the British Medical Association may from time to time select in any department of ophthalmic medicine or surgery. The Council is prepared to consider the award of the prize in the year 1947 to the author of the best essay on: "The Aetiology and Treatment of Chronic Iridocyclitis." Essays submitted in competition must reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, on or before Dec. 31, 1946. Each essay must be signed with a motto and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author. In the event of no essay being of sufficient merit the prize will not be awarded in 1947.

Branch and Division Meetings to be Held

DERBYSHIRE BRANCH.—At Smedley's Hydro, Matlock, Sunday, Dec. 22, 2.30 p.m. Meeting of Branch Council. Agenda: Election of Officers, etc.

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, Dec. 19, 7.15 p.m. Clinical demonstration by Mr. George Y. Feggetter: Some Genito-urinary Conditions. 3.45 p.m. Address by Dr. C. C. Ungley: Pernicious Anaemia and Subacute Combined Degeneration of the Cord—A survey of 20 years' progress.

PADDINGTON DIVISION.—At Inoculation Department, St. Mary's Hospital, W., Thursday, Dec. 19, 8.30 p.m. Sir Alexander Fleming, F.R.S.: Penicillin in General Practice. Members of other Divisions are invited to attend.

RETURN TO PRACTICE

The Central Medical War Committee announces that the following have resumed civilian practice: Dr. F. Dudley Hart, at 152, Harley Street, W.1 (Tel.: Welbeck 6919); Mr. J. Stewart Heslop, F.R.C.S., at 8, St. John Street, Manchester, 3 (Tel.: Blackfriars 2166); Dr. John S. Parkinson, at 10, St. John Street, Manchester, 3 (Tel.: Blackfriars 4311); Dr. J. Graham Scott, at 11, Wexford Avenue, Johannesburg, S. Africa; Dr. R. J. Twort, at 11, Park Terrace, Nottingham (Tel.: Nottingham 66486).

Meetings of Branches and Divisions

SALISBURY DIVISION

A successful meeting of the Division was held on Nov. 27. Thirty members and visitors were present, with Dr. A. D. H. Simpson in the chair; Dr. G. D. Kersley, of Bath, was the guest of the Division.

Dr. Kersley addressed the meeting on "The Differential Diagnosis and Treatment of Rheumatoid Arthritis," showing slides of the x-ray appearances in gout, rheumatoid arthritis, and other conditions. During the discussion that followed doubt was expressed as to the amount of progress made in treatment in the last twenty years. The lecturer, in reply, emphasized the change of outlook in the profession itself. Such cases were now regarded as meriting special care and extensive physical and orthopaedic treatment. The institution in the future of establishments for rheumatoid cases on the lines of tuberculosis sanatoria was probable.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

General Meeting of Fellows.—Tues., 5.30 p.m. Ballot for election to the Fellowship.

Section of Pathology.—Tues., 8.15 p.m. Discussion: Thrombosis. Openers: Mr. H. J. B. Atkins: Clinical aspects of thrombosis. Dr. R. H. D. Short: Pathology of primary thrombosis. Dr. Helen Payling Wright: Platelet changes in thrombosis. Prof. H. P. Gilding: Anticoagulants and their mode of action.

Section of Dermatology.—Thurs., 5 p.m. (Cases at 4 p.m.) Paper by Dr. W. J. Hohmann: Erythematous initial tuberculide.

HUNTERIAN SOCIETY.—At Pimm's in the Poultry, Mon., 7.15 p.m. Dinner meeting. Discussion by Dr. Geoffrey Evans: Flatulence.

MEDICAL SOCIETY OF LONDON. 11, Chandos Street, Cavendish Square, W.—Mon., 8.30 p.m. Lloyd Roberts Lecture by Sir James Chadwick, F.R.S.: Atomic Energy and some Applications to Medicine.

WEEKLY POSTGRADUATE DIARY

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, W.C.—Mon. 5 p.m., Dr. A. D. Porter: Vitamin A in Dermatology. Tues. 5 p.m., Dr. H. Corsi: Diseases of the Nails.

APPOINTMENTS

DAVIS, HAROLD, M.B., B.Chir., M.R.C.P., Honorary Physician to Outpatients, Hampstead General and North-West London Hospital, Haverstock Hill, N.W.

LAMA, ADRIAN, M.B., Ch.B., D.O.M.S., Ophthalmic Surgeon to the Peter and Kinross Joint County Council Education Authority and Visiting Ophthalmic Surgeon to the Bridge of Eam Hospital.

RINKEL, L. RONALD J., M.R.C.S., L.R.C.P., Medical Superintendent, Binal Legio Sanatorium, Nayland, near Colchester.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than fast post Monday morning.

BIRTHS

BLACK.—On Nov. 30, 1946, in Leeds, to Stella, wife of George Black, F.R.C.S., a daughter.

BROCK.—On Nov. 27, 1946, at King's College Hospital, to Margaret (née Cave), wife of Dr. Bevis Brock, a son—Christopher.

CLIFT.—On Dec. 1, 1946, to Dorothy (née Newell), M.B., Ch.B., wife of A. J. Clift, F.R.C.S., a son.

DE COVERLEY.—On Sept. 20, 1946, at Maymyo, Burma, to Jeao (née Draz White), M.B., B.S., wife of Roger de Coverley, a second daughter.

DE SOLDERHOFF.—On Dec. 2, 1946, at Ayrshire Central Hospital, to Mollie, wife of Richard de Solderhoff, F.R.C.S.Ed., M.R.C.O.G., a son.

HUTTON.—On Dec. 1, 1946, at Harpendee Auxiliary Hospital, to Dorothy (née Cheshire), wife of Dr. T. B. Hutton, a brother for David—Christopher Thomas.

LOYD OWEN.—On Dec. 8, 1946, at the Lindo Wing, St. Mary's Hospital, W.1, to Helen, wife of Dr. Morus W. Lloyd Owen, 50, Howard Road, Coulsdon, Surrey, a daughter.

ORTON.—On Dec. 1, 1946, to Ena, wife of R. Orton, M.B., Ch.B., D.P.M. Rutherford, Garlands, Carlisle, a daughter.

RIVETT.—On Dec. 8, 1946, at the Willows Nursing Home, Bramley, Leeds, to Elspet (née Strathie), wife of Dr. P. A. H. Rivett, a daughter.

WATSON.—On Nov. 23, 1946, at Royd Lodge, Victoria Road, Bridlington, to Dorothy, wife of Edgar S. Watson, O.B.E., M.B., Ch.B., a son.

WILLIAMS.—On Dec. 9, 1946, at Hampstead, to Joy B. (née Jewsoo), M.B., B.S. of Denis Williams, a daughter.

WRIGHT.—On Dec. 3, 1946, in Nyasaland, to Marjorie (née Wood), wife of Robert Wright, M.B., B.Chir., a son—John Garnett.

Dangerous Drugs Act: Withdrawal of Authority

The Home Office announces that Dr. Halina Sulinska (London, N.W.3) is no longer authorized to be in possession of or to prescribe those drugs to which the Dangerous Drugs Regulations apply.

A SURVEY OF THE OUTCOME OF 20 CASES OF *H. INFLUENZAE* MENINGITIS RELATED TO BACTERIAL TYPE

BY

K. ZINNEMANN, M.D.

Lecturer in the Department of Pathology and Bacteriology, School of Medicine, Leeds

Considerable progress in the treatment of *H. influenzae* meningitis has been made since Margaret Pittman (1931) showed that most strains isolated from this condition belong to the serological type b—one of six types all characterized by possessing capsules composed of polysaccharides. Early efforts at specific treatment were directed towards producing an effective type-specific *H. influenzae* antiserum (Pittman, 1933; Wilkes-Weiss and Huntington, 1936; Fothergill, 1937). These succeeded in reducing the fatality rate only from 97% without specific treatment (Lindsay, Rice, and Selinger, 1940) to 80–84%. The sera used by Pittman and others were prepared by immunizing horses. In 1936 Horsfall, Goodner, and MacLeod showed that in the case of type-specific pneumococcus serum the therapeutic qualities of rabbit sera are superior to those of horse sera. They explained this finding as most probably due to the smaller size of the antibody molecule in rabbit serum, which diffuses more readily into infected foci and so combines more effectively with the antigen. Excess of horse serum also causes a prozone effect which is not obtained with rabbit serum. These inferior combining qualities of horse antiserum may be responsible for the poor therapeutic results of Pittman, of Wilkes-Weiss and Huntington, and of Fothergill, since there are close analogies in the antigenic structures of pneumococci and *H. influenzae* (Pittman, 1931; Alexander, 1943a).

The introduction of sulphonamide therapy made an effective antibacterial treatment a practical possibility for the first time. The results were reviewed in this country by Mutch (1941) and by J. Gordon, Woodcock, and Zinnemann (1944). In a series of papers Alexander, Heidelberger, and collaborators (1939, 1940, 1942, 1943a, 1943b, 1944), in *in vitro* and mouse experiments as well as in clinical trials, laid the foundations for a rational therapy based on a combination of the most effective sulphonamide—i.e., sulphadiazine—with rabbit anti-*H. influenzae* type b serum. Alexander (1944) thus succeeded in reducing the mortality rate to 22% in a total of 87 patients all treated within 7 years. In a report which was only seen when this survey was going to press Smith, Wilson and Hodes (1946) give an account of 28 cases of *H. influenzae* meningitis treated with the combination of sulphonamides and *H. influenzae* type b rabbit antiserum. The recovery rate was 85.7%.

Experience of this condition is comparatively slight in this country, as cases occur only sporadically over a wide area. From a number of case reports it seemed as if sulphonamide therapy alone might be sufficient (J. Gordon, Woodcock, and Zinnemann, 1944). As reports of more cases accumulated it became evident, however, that this therapy was proving disappointing in many instances. Recently Alexander (1944) pointed out "that the capacity of the sulphonamides to effect complete recovery from type b *H. influenzae* infection is influenced by two factors. First, the infection must be relatively mild. Secondly, the drug must be started early in the course of the infection. It is believed that only under such conditions will sufficient time be afforded to the patient to produce through his own powers sufficient antibody to overcome the disease."

The Emergency Public Health Laboratory Service has now secured a small stock of *H. influenzae* type b specific rabbit antiserum. Thus it is possible to make practical use of the typing of *H. influenzae* strains isolated from meningitis—a pro-

cedure advocated recently in this country (Mutch, 1941; J. Gordon, Woodcock, and Zinnemann, 1944). An outline of the main points of Alexander's (1943b, 1944) routine treatment may therefore be useful.

All material necessary for the isolation of the causative organism and for typing should be collected before, starting specific treatment. The capsule-swelling technique carried out on the organisms in the C.S.F. is the quickest way of establishing the type of *H. influenzae*. To confirm the result typing by agglutination on a slide and/or in tubes should be carried out with the isolated strain. Using the agglutination tests alone will delay the result for 24 to 48 hours.

1. The first dose of sulphonamide—sulphadiazine or sulphamezathine—is given intravenously.

2. A continuous intravenous saline drip is established for 24 hours. The remainder of the daily dose of sulphonamide—i.e., 0.1 g. per kg. body weight in all—should be added to the drip. After the first 24 hours sulphonamide therapy is continued by mouth. The daily dose is 0.1 g. per kg. body weight, and is continued until 7 days after the C.S.F. is first shown to be sterile. Earlier cessation of sulphonamide treatment carries the risk of relapse.

3. The dose of specific serum to be administered is roughly determined by the glucose content of the C.S.F. Alexander (1943b) describes a simple adaptation of Benedict's qualitative method for quick determination of the sugar content of C.S.F. The specific antibody present in the therapeutic serum is given in milligrams of antibody nitrogen. The accompanying Table is a guide to the dosage of antiserum.

Table showing Dosage of *H. Influenzae* type b Rabbit antiserum based on Glucose Content of C.S.F.

Glucose in C.S.F. (mg. per 100 ml.)	Indicated Dose of Antibody Nitrogen (mg.)
<15	100
15–25	75
25–40	50
>40	25

4. The patient's progress is judged to a large extent by the changes in the C.S.F., which is examined daily. If within 24 hours sugar and chlorides have risen, no organisms are seen in direct smears, and the patient's serum causes capsular swelling when diluted 1 in 10 no further serum is required provided the C.S.F. continues to become normal; cultures become and remain sterile; and free antibody as shown by the capsular swelling test persists in the serum in adequate excess. If progress is not satisfactory at the end of 48 hours from the initiation of serum therapy a further dose equivalent to 25 mg. of antibody nitrogen should be given intrathecally.

5. Alexander's last clinical report (1944) is mainly concerned with protracted cases and cases belatedly subjected to specific treatment, which she terms "chronic *H. influenzae* meningitis," though in our view subchronic or subacute *H. influenzae* meningitis would seem to describe the condition more adequately, since the expectation of life can be measured in weeks or months and not in years. In Alexander's report two histories are given in which a striking improvement followed intrathecal introduction of air together with antiserum. She suggests that adhesions blocking the flow of fluid in the cerebrospinal canal are loosened, and she also advocates the injection of heparin intrathecally to prevent clotting.

Observations on Penicillin and Streptomycin Sensitivity

It was emphasized repeatedly in the early investigations of the antibiotic properties of penicillin that *H. influenzae* is an

outstanding example of an organism resistant to this substance. When supplies of penicillin became more ample higher concentrations could be employed and strains of *H. influenzae* were found to be sensitive to these. Straker (1945) reported two such strains, and she thought that smooth strains were more sensitive than respiratory ones. Private communications (K. B. Rogers, J. M. Croll, F. W. Gunz, and C. J. Young) supported the impression that penicillin had its uses in *H. influenzae* meningitis. M. Gordon and Zinnemann (1945), in a survey of the penicillin-sensitivity of a large collection of *H. influenzae* strains, established that this was not an occasional phenomenon; 43 respiratory and 18 meningeal strains were all found to be sensitive to penicillin, most of them in concentrations which allowed a rational use of the drug in conditions due to this organism. Three case reports of successful penicillin treatment, in combination with sulphonamides, of *H. influenzae* meningitis have been published hitherto (Forgacs, Hutchinson, and Rewell, 1945; McIntosh and Drysdale, 1945; Drysdale, McIntosh, and Brodie, 1946).

Quite recently, use of the new antibiotic streptomycin, mostly in combination with sulphonamides, has been reported in 6 cases of *H. influenzae* meningitis (Anderson and Jewell, 1945; Herrell and Nichols, 1945; Cairns, Duthie, and Smith, 1946). So far as can be judged, fairly large doses of streptomycin are required. Hewitt and Pittman (1946) find that cultures of *H. influenzae* show a decreasing sensitivity to antibiotics in the following order: streptomycin, penicillin X, and penicillin. Mouse experiments confirm the *in vitro* findings. The results of further clinical trials have to be awaited before their respective merits can be judged. Hewitt and Pittman's experiments suggest also that a synergistic action may take place when these antibiotic substances are combined with sulphonamides or specific rabbit antiserum.

Below are presented reports of 20 cases of *H. influenzae* meningitis treated in various ways. The survey is the result of inquiries made at a number of laboratories and hospitals from which strains of *H. influenzae* were received in this department for typing. The clinical details are those kindly given to me by the physicians under whose care the patients were placed and the pathologists concerned. These circumstances account for the diverse methods of treatment and dosage used.

Cases treated with Sulphonamides Only

Case 1.—J. M., a boy aged 1 year 5 months. (Under the care of Prof J. C. Spence, Royal Victoria Infirmary, Newcastle-upon-Tyne.) Onset of symptoms 5/1/45. No special treatment at home. On admission on 24/1/45 signs of meningitis. C.S.F. turbid—cell count 13,000 per c.mm., no sugar present; *H. influenzae* type b isolated. Medication started with 2 g. sulphathiazole intravenously; subsequently 0.25–0.5 g. sulphathiazole by mouth 4-hourly for 13 days. Total amount given, 34 g. A clinical relapse was experienced on 31/1/45, when the dose of sulphathiazole was reduced from 3 g. to 1.5 g. per day. The cell count in the C.S.F. rose from 800 per c.mm. to 1,500 per c.mm. during the relapse. After discontinuation of sulphathiazole on 6/2/45 the cell count was still 800 per c.mm. Sulphadiazine therapy was therefore started on 12/2/45 with 0.5 g. 4-hourly for 18 days, and 0.25 g. 4-hourly for another 26 days. The sugar content of C.S.F. was normal from 12/2/45 onwards. After an initial rise to 1,200 on 15/2/45 the cell count in the C.S.F. declined slowly until it reached the figure of 30 cells per c.mm. on 9/3/45, at which level it remained with slow but steady clinical improvement until the child was discharged in normal physical and mental condition on 9/4/45. The total dosage of sulphadiazine given was 97 g.

Case 2.—M. S., a girl aged 3 years. (Under the care of Dr. M. L. Bery, Lincoln.) On 5/11/44 headache; a squint was noticed on the same day. Admitted on 8/11/44 with symptoms of meningitis. T. 101° F. (38.3° C.). Lumbar puncture: C.S.F. under pressure and milky in appearance. Treatment started with 1.5 g. sulphathiazole, then 0.5 g. 4-hourly for 3 days. When 9 g. had been administered the temperature had returned to normal although the pulse remained rapid. Therapy was discontinued and the temperature rose again to 104° F. (40° C.). *H. influenzae* type b isolated 15/11/44. A second course of sulphathiazole was started on 16/11/44, but was discontinued owing to vomiting. The total of sulphathiazole given in the two courses was 13.5 g. From then onwards the child's condition deteriorated slowly. A 3-day course of sulphanilamide amounting to a total of 105 g. was given from 27/11/44 to 30/11/44 with no effect. Death occurred on 1/1/45.

Case 3.—P. E., a girl aged 1 year 10 months. (Under the care of Dr. T. M. Pole, Grantham Hospital.) On 25/5/44 she fell ill

suddenly with violent vomiting of increasing severity. She was given 8 g. sulphanilamide before admission on 26/5/44, when she was stuporous but without neck rigidity, and Kernig 2+. T. 97° F. (36.1° C.). Chest: terminal congestion with generalized loose rales. C.S.F. not under pressure but turbid. A course of sulphapyridine was started at once, but the condition deteriorated rapidly. On 27/5/44 *H. influenzae* type b was isolated. The child died the same day, 24 hours after admission.

Case 4.—R. M., a boy aged 9 months. (Under the care of late Dr. T. D. Semple, Cumberland Infirmary, Carlisle.) Was admitted to hospital on 2/5/44 after having been ill for 3 days with meningitic symptoms for 2 days. Treatment was started with 0.25 g. oral sulphathiazole 4-hourly for 5 days. Then medication was reduced to 3 daily doses for 3 days. As all symptoms had subsided treatment was then discontinued for 5 days. When symptoms recurred medication was started again with 6-hourly at 8-hourly doses of 0.25 g. sulphathiazole. 24/5/44: *H. influenzae* type b isolated. 26/5/44: Administration of sulphadiazine 4-hourly doses of 0.5 g. for 2 days, after which time the treatment had to be discontinued because of failure to pass urine for 16 hours. During the next 3 days meningitic symptoms became more marked and another course of 0.25 g. sulphadiazine 4-hourly was given until swallowing became difficult on 2/6/44. Death occurred on 4/6/44. The total dose of sulphathiazole was 19.5 g. and of sulphadiazine 7 g.

Case 5.—Baby A. S.; no age stated. (Under the care of Dr. M. Lawson, Berwick-on-Tweed.) A week before admission on 13/2/45 the boy developed a left-sided lobar pneumonia and was given sulphapyridine with satisfactory result. On 11/2/45 a renewed rise of temperature, with vomiting. Another course of sulphapyridine was started the same day. On admission to hospital on 13/2/45 there was slight neck rigidity; the fontanelles were bulging. Lumbar puncture 20 ml. of a turbid fluid was withdrawn under pressure. There was an impaired note over the left side of the chest. Sulphapyridine medication was continued together with chloral hydrate, gr. 7 (0.45 g.) at night. On 16/2/45 there were increased signs of meningitis and cerebral irritation, left intern strabismus, extreme neck rigidity, and fits. Pulse rate very rapid. After a slight improvement on 17/2/45 the child died next day. The *H. influenzae* strain isolated from the C.S.F. was subsequently found to be of type b.

Cases treated with Sulphonamides and Penicillin

Case 6.—This boy, M. L., aged 2 years 7 months (under the care of Dr. J. O'Connor, Brumby Isolation Hospital), had been ill with symptoms suggestive of tuberculous meningitis for two weeks. Two days before being admitted to hospital, vomiting, headache, and cough increased; T. 101° F. (38.3° C.), P. 140, R. 36. There was evident neck rigidity on admission on 23/6/45; 1 g. sulphanilamide was given 4-hourly. 29/6/45: No change in condition. Course of sulphanilamide completed; 10,000 units antimeningococcal serum given. 30/6/45: 30,000 units intramuscular penicillin 3-hourly for 5 days. 4/7/45: No change; penicillin discontinued. 5/7/45: 0.25 g. sulphasuxidine 8-hourly. On 7/7/45, C.S.F. withdrawn under pressure. 10 ml. antimeningococcal serum given intrathecally. *H. influenzae* type b reported grown from the specimen of C.S.F. 10/7/45: 0.5 g. sulphathiazole 8-hourly for 3 days. 17/7/45: Very ill; paralysis in left arm, horizontal nystagmus; T. 105° F. (40.6° C.), pulse very rapid, R. 60. 18/7/45: Died at 4 a.m. after preceding hyperpyrexia of 109° F. (42.5° C.). Later investigation showed the strain to be completely inhibited by 0.5 unit penicillin per ml. of medium.

Case 7.—This 5-year-old girl, J. H. (under the care of Dr. L. Cole, Addenbrooke's Hospital, Cambridge, and Mr. D. W. C. Northfield, Chase Farm Hospital, London), had a 3-days history of headache and vomiting before admission to hospital on 14/3/45. There were marked head retraction and an acute infection of the left knee-joint. C.S.F. under pressure 350 mm.; opaque, containing 5,400 polymorphonuclear leucocytes per c.mm. Protein, 80 mg. per 100 ml.; glucose diminished. Pure growth of *H. influenzae*; the colonies of the strain had a rough surface, growth being rather dry. No agglutination with any of the 6 type sera at either 37° C. or 56° C. The strain was diagnosed as belonging to the respirator group of *H. influenzae*. Puncture of the left knee produced thick pus containing Gram-negative bacilli. On culture a heavy growth of *H. influenzae* was obtained. Our investigations showed that the strain was inhibited by 1 unit penicillin per ml. of medium. During the first week in hospital the child was treated with sulphathiazole and penicillin, 30,000 units of the latter being administered 3-hourly by the intramuscular route and 20,000 units per day intrathecally. Sulphathiazole medication was discontinued after 8 days when it was found that the strain was sulphathiazole-resistant. In all, the child had received 93.5 g. sulphathiazole in 8 days. Penicillin therapy was continued until 4/4/45. Great irritability made administration of paraldehyde 2 ml. i.m. necessary. On 4/4/45 the general condition was still very poor; the child was drowsy and unstable, and had marked head retraction. Medication discontinued, the case

being considered as hopeless, although daily lumbar punctures were performed until 14/4/45. Slow improvement set in during April, and by 2/6/45 the general condition was such that the patient was considered fit for discharge. On the evening of that day she suddenly began to vomit. 8/6/45: Sixth-nerve palsy, flaccid limbs, especially on the right side, very drowsy, vomiting, divergent squint. On the following day the left pupil was larger than the right. There were 41,000 white blood cells per c.m.m. On 12/6/45 the child was deeply comatose, with a slow pulse rate and occasional vomiting. A diagnosis of brain abscess was made and she was transferred to Chase Farm Hospital on that day for neurosurgical treatment. Examination revealed the following signs: Comatose. No papilloedema. Bilateral prosis. Absent corneal reflexes. Fluctuating spasticity of right upper and both lower limbs. Bilateral extensor plantar responses. The C.S.F. was cloudy, the pressure too low for measurement; culture sterile. Exploratory tapping revealed a left post-frontal abscess, and 30 ml. of thick pus was aspirated with immediate improvement in her condition. Pure growth of *H. influenzae* was obtained from the pus. Aspiration was repeated on 18/6/45, and on 20/6/45 an osteoplastic craniotomy was performed and the abscess contents evacuated and drained. Considerable temporary improvement followed, but by 7/8/45 she suffered from symptoms of a further collection of pus in the abscess cavity, which was confirmed by re-aspiration. On 11/8/45 further operation was carried out, when the abscess was totally enucleated. It was extending into the temporal and parietal regions and measured 6 cm. in diameter. Gram-negative bacilli were seen in the direct film, and culture yielded *H. influenzae*. Progress after this operation was rapid. The patient started walking on 31/8/45 and was discharged on 5/9/45, walking fairly well but a little unsteady and with a slight limp. Mentally she was alert, bright, and bappy. On re-examination on 12/10/45 she was normal apart from the right arm jerks being slightly brisker than the left.

Case 8.—A boy, M. E., aged 2 years (under the care of Dr. J. F. Gaskell, Addenbrooke's Hospital, Cambridge), started being sick and feverish on 16/10/45. Admitted on 20/10/45 with obvious signs of meningitis. C.S.F. turbid with clots; Gram-negative bacilli in direct film. Growth of *H. influenzae* belonging to Pittman's type b. The strain was completely inhibited by 1 unit penicillin per ml. of medium. Therapy with intramuscular and intrathecal penicillin as well as sulphamezathine was started. *H. influenzae* was isolated from the C.S.F. until 27/10/45. It is stated that from 31/10/45 to 2/11/45 the C.S.F. exerted a bacteriostatic activity in a dilution of 1 in 32. The fluid was still purulent but sterile on 1/11/45. On 4/11/45 the patient died. Post-mortem examination revealed a purulent meningitis and hydrocephalus. A total of 22.5 g. sulphamezathine was given in 8 days, of 600,000 units penicillin intramuscularly in 17 days, and of 258,000 units intrathecally in 6 days.

Case 9.—K. L., a boy aged 3 years (under the care of Dr. L. B. Cole, Addenbrooke's Hospital, Cambridge), started a cough on 20/10/45. On 24/10/45 he complained of aching bones and cold feet. He started vomiting on 25/10/45, and next day had opisthotonos, photophobia, and a squint. He was admitted on 27/10/45 with obvious meningitis and a temperature of 104° F. (40° C.). The C.S.F. was purulent and yielded a heavy growth of *H. influenzae* of type b. The strain was found to be completely inhibited by 1 unit penicillin per ml. of medium. Therapy: Sulphamezathine, penicillin intramuscularly and intrathecally. The reports on findings in the C.S.F. during treatment are as follows. 29/10/45: Bacteriostatic activity, 1 in 2. 30/10/45: Bacteriostatic activity, 1 in 4. 31/10/45: Bacteriostatic activity, 1 in 16. 1/11/45: Bacteriostatic activity, 1 in 32+. 2/11/45: Bacteriostatic activity, 1 in 32; fluid cloudy, Gram-negative bacilli in direct film; culture sterile. 3/11/45: 120 white blood cells per c.m.m. Growth of penicillin-resistant *H. influenzae*. 5/11/45: Culture sterile. Patient discharged well on 14/11/45.

Total sulphamezathine given	15 g. in 3 days
penicillin given I.M.	995,000 units in 10 days
" " I.T.	200,000 " " 8 "

Case 10.—R. M., a boy aged 1 year 4 months. (Under the care of Dr. L. B. Cole, Addenbrooke's Hospital, Cambridge.) On 11/10/45 the child was unwell and drowsy, and vomited once. Admitted to hospital on the same day with obvious meningitis. The C.S.F. on 12/10/45 was cloudy and contained many pus cells and Gram-negative bacilli. The strain isolated was of type b, and was completely inhibited by 2.5 units penicillin per ml. of medium. Two courses of 690,000 units penicillin intramuscularly were necessary, the first from 13/10/45 to 19/10/45, the second from 20/10/45 to 26/10/45. Two courses of sulphamezathine were also given, the first from 12/10/45 to 18/10/45, with a total dose of 20 g., and the second from 22/10/45 to 27/10/45, with a total dose of 16.5 g. As *H. influenzae* could still be isolated from the C.S.F. one intrathecal injection of penicillin was given on each of the following days: 26/10/45 (6,000 units), 28/10/45 (8,000 units), and 30/10/45 (25,000 units). On 1/11/45 the C.S.F. showed no bacteriostatic activity. The child improved rapidly after 30/10/45,

and recovered, developing chickenpox as a complication. Discharged well on 29/11/45.

Case 11.—M. G., a boy aged 1 year 3 months. (Under the care of Dr. G. W. Anderson, Preston Hospital, North Shields.) Three weeks before admission the child had bronchopneumonia, which cleared up satisfactorily. Two weeks later he vomited and was fretful, and symptoms suggestive of tuberculous meningitis set in 2 days before admission on 10/3/45. A total of 6 g. sulphathiazole had been given by the practitioner. The course of sulphathiazole was continued with 4-hourly doses until on 17/3/45 the isolation of *H. influenzae* was reported. The strain was subsequently shown to be of type b and to be completely inhibited by 1 unit penicillin per ml. of medium. On receiving the bacteriological report 50,000 units penicillin were given intrathecally by the cisternal route and the same amount by lumbar puncture, also 20,000 units 3-hourly intramuscularly. In addition he received 4-hourly doses of 0.5 g. of sulphadiazine. On the second day the penicillin content of the C.S.F. was 100 units per ml. and the culture was sterile. This medication was maintained for 7 days with the exception of 1 day when no cisternal puncture was performed and of 2 days when the administration of sulphadiazine had to be stopped because of crystal formation in the urine. By 23/3/45 the general condition had improved; the C.S.F. had been sterile for 6 days although many pus cells were still present. During this time the penicillin content of the C.S.F. was between 50 and 100 units per ml. A total of 15 g. sulphadiazine and 720,000 units penicillin intrathecally and 480,000 units intramuscularly had by then been given. All medication was discontinued, but on 25/3/45 the temperature, which had until then been normal for 5 days, rose again to 100° F. (37.8° C.). After another 2-day course of sulphadiazine a marked improvement was noticeable in the general condition, but the child seemed to be blind. From 28/3/45 to 5/4/45 there appeared to be slow but satisfactory progress, although sight did not return. On 5/4/45 the child died. At necropsy there was a little organizing pus on the tips of the temporal lobes and on the surface under the pons. Cultures from all these accumulations of pus were sterile with the exception of one from a temporal lobe, from which 2 colonies of *H. influenzae* were grown. There was a very marked internal hydrocephalus, with the lateral ventricles grossly enlarged, reducing the cerebral tissue to a thin layer.

Case 12.—The boy, A. C., aged 3 (under the care of Dr. J. Allan, Grantham Hospital), was admitted on 3/11/45, three days after having fallen ill with drowsiness and vomiting. He presented head retraction, flexion and adduction of left leg, Kernig's sign +, convergent squint of the left eye, and twitchings of the face. T. 100° F. (37.8° C.), P. 120, R. 36. Lumbar puncture produced a cloudy fluid under increased pressure. Administration of sulphathiazole 0.75 g. 4-hourly was started. On 7/11/45 the condition had become worse. There were convulsions, biting of the tongue, violent twitchings of limbs, and the C.S.F. was thickly purulent. Fifteen ml. was withdrawn by lumbar puncture and 60,000 units calcium penicillin in 6 ml. were given intrathecally, also 20,000 units intramuscularly, followed by 10,000 units 3-hourly. On the following day another 50,000 units penicillin were given intrathecally. On 10/11/45 there were numerous pus cells, Gram-negative bacilli, and filaments. No acid-fast bacilli present. Pure growth of *H. influenzae*. The strain was subsequently found to belong to type b and to be completely inhibited by 1 unit penicillin per ml. of medium. A further 40,000 units penicillin were given intrathecally on 10/11/45 and 17/11/45. On 18/11/45 the condition had not changed appreciably. Ten ml. of rabbit *H. influenzae* type b antiserum (made in Leeds) was given intramuscularly. Sulphathiazole was discontinued. A blood sample taken next day did not show any noticeable antibody in a dilution of the patient's serum of 1 in 10. A daily dose of 6 g. sulphadiazine was given from 19/11/45 to 30/11/45. Between 20/11/45 and 27/11/45 the leucocyte count varied from 14,000 to 12,950 per c.m.m. No marked change in the general condition. On 30/11/45 the condition was still without change; a cisternal puncture was performed. 10 ml. C.S.F. was withdrawn and 6 ml. of rabbit *H. influenzae* type b antiserum injected, together with 70,000 units calcium penicillin. The C.S.F. showed pus cells and Gram-negative bacilli. A moderate growth of *H. influenzae* type b was obtained on culture. On 4/12/45, when the child was comatose, another cisternal puncture, with subsequent intrathecal injection of 10 ml. rabbit *H. influenzae* type b antiserum and 30,000 units calcium penicillin, was carried out. The withdrawn C.S.F. gave only a scanty growth of *H. influenzae* type b, and it contained numerous pus cells. Henceforth treatment was discontinued. The coma deepened and the child died in the early morning of 6/12/45. A total of 37.75 g. sulphathiazole, of 66 g. sulphadiazine, of 2,160,000 units penicillin intramuscularly and 370,000 units intrathecally had been administered during the course of the illness. At necropsy thick green pus was found in the lateral ventricles. No pus elsewhere on the brain.

Case 13.—According to the history given, A. R., a boy of 1 year 2 months (under the care of Prof. W. C. Vining, General Infirmary at Leeds), had a pneumonia 6 weeks before admission on 17/12/45.

This condition cleared up satisfactorily within a week under sulphonamide therapy. At the end of the week he was allowed to get up, but started vomiting the following day and continued to do so until admitted to hospital. The child presented obvious signs of meningitis; he was very dehydrated, listless, and did not respond. T. 97° F. (36.1° C.), P. 150, R. 20. Lumbar puncture produced a cloudy fluid under pressure. Cell count in C.S.F., 760 per c.mm.; proteins, 200 mg. per 100 ml.; chlorides, 0.64%. Direct film showed pus cells and Gram-negative bacilli, of which some were filament-forming; pure heavy growth of *H. influenzae* type b. Subsequent tests showed the strain to be completely inhibited by 2.5 units penicillin per ml. of medium. On 18/12/45 a course was started of 25,000 units penicillin intrathecally per day and of 16,000 units intramuscularly every 3 hours, supported by 0.5 g. sulphadiazine 4-hourly. 19/12/45: Sugar content of C.S.F., 40 mg. per 100 ml. 20/12/45: Sugar content, 70 mg. per 100 ml. One ml. of C.S.F. contained 32 units penicillin. Only scanty Gram-negative bacilli in film. Culture gave but a small number of colonies of *H. influenzae* type b. 21/12/45: Sugar content of C.S.F., 60 mg. per 100 ml. An occasional Gram-negative bacillus was seen in the direct film, which showed numerous pus cells. Only scanty growth of *H. influenzae* type b was obtained. Agglutinating antibodies against *H. influenzae* type b were present in the undiluted serum, but not in dilution 1 in 10. 22/12/45: No change. Lumbar puncture unsuccessful. C.S.F. from cisternal puncture showed abundant pus cells. No organisms seen. No growth was obtained on culture. Penicillin content more than 1/8 but less than 1/4 unit per ml. On 23/12/45 no intrathecal treatment was given. 24/12/45: Child going downhill. C.S.F. contained pus cells but no organisms; no growth obtained on culture. Penicillin content, 1/4 unit per ml. 25/12/45: C.S.F. sterile; penicillin content, 1/2 unit per ml. On 26/12/45 the child was very weak. Lumbar and cisternal punctures and injection of penicillin by both routes were carried out. Both fluids were sterile on culture and showed only a few pus cells in the direct film. The child died shortly after the cisternal puncture. A total of 24.5 g. sulphadiazine, 992,000 units penicillin intramuscularly and 200,000 units intrathecally was administered within 9 days. At necropsy the brain was under considerable tension. The convolutions were flattened, and over both vertex and base there was a sticky fibrinous exudate of yellowish colour. No growth was obtained from the exudate. Both ventricles were extended and contained clear fluid. The pia mater of the spinal cord showed a fibrinous exudate similar to that on the surface of the brain. Death from cerebral compression.

Case 14.—A detailed account of this case has been given by McIntosh and Drysdale (1945). This girl of 2½ years had *H. influenzae* type b meningitis following closely on a meningococcal meningitis. The type b *H. influenzae* strain was completely inhibited by 0.5 unit and partially inhibited by 0.25 unit penicillin per ml. of medium. Initial symptoms observed were those of an upper respiratory catarrh suggestive of the invasive stage of measles. Two days later obvious meningitis had developed. A 7-days course of 75,000 units penicillin intrathecally and of sulphapyridine by mouth resulted in apparent success, but 2 days later a relapse occurred. A 12-days course of penicillin intrathecally and intramuscularly as well as 7 days' administration of sulphamerazine led to complete restitution. In all, 20 g. sulphapyridine, 22.5 g. sulphamerazine, 325,000 units penicillin intrathecally, and 1,200,000 units intramuscularly were administered.

Case 15.—B A., a girl of 1 year 8 months (under the care of Dr. R. L. Langley, Bradford Children's Hospital), fell suddenly ill on 14/5/45 with vomiting, deliriousness, and temperature. On admission the following day she was semi-comatose, with neck rigidity; Kernig's sign +; abdominal and patellar reflexes absent. Lumbar puncture produced a turbid fluid under normal pressure, which contained 1,200 polymorphonuclear leucocytes, 100 lymphocytes, and 480 red cells per c.mm. The culture grown from the C.S.F. was an *H. influenzae* type b which was completely inhibited by 1 unit and partially by 0.5 unit penicillin per ml. of medium. Treatment consisted of daily lumbar punctures with intrathecal injection of 10,000 units penicillin each time for 4 days, 3-hourly intramuscular injection of penicillin for 7 days, and sulphathiazole by mouth for the first 4 days. On 19/5/45 the C.S.F. was clear for the first time; the temperature still kept moving. The child improved gradually, her temperature being normal from 29/5/45. Recovery was complete. Total amount of penicillin given intrathecally was 40,000 units, intramuscularly 259,000 units; and of sulphathiazole 9.5 g.

Case 16.—M. W., a girl aged 1 year (under the care of Dr. L. Watson, Clayton Hospital, Wakefield), was admitted to hospital on 17/1/46 with the history of a fall off a chair 3 ft. (0.9 m.) high. The fall landed her on the back of her head. She was able to play for about 50 minutes afterwards and then became drowsy. She was admitted to a surgical ward for consultation, and was transferred to a medical ward on 23/1/46, when there were signs of meningitis with neck rigidity and slight stiffness of the back. A lumbar puncture carried out 2 days previously had given the follow-

ing results: fluid under pressure, markedly turbid. Protein, 60 mg. per 100 ml.; chlorides, 750 mg. per 100 ml.; cells, 7,600 per c.mm. The centrifuged deposit showed large numbers of polymorphonuclear leucocytes, some lymphocytes, and numerous Gram-negative bacilli. Culture yielded *H. influenzae*, which subsequently was found to belong to Pittman's type b and to be sensitive to penicillin. Combined penicillin-sulphathiazole therapy was instituted as follows: Thirty thousand units of penicillin 3-hourly intramuscularly and 1 dose of 0.5 g. sulphathiazole followed by 0.25 g. 4-hourly from 23/1/46 to 26/1/46. As there was no marked improvement the dose of penicillin was increased to 50,000 units 3-hourly for a further 8 days and sulphathiazole was continued until 28/1/46. On 29/1/46 another lumbar puncture was carried out and 8,500 units penicillin given intrathecally. The pressure of the C.S.F. was 150 mm. and the fluid was slightly turbid; protein, 70 mg. per 100 ml.; chloride, 735 mg. per ml.; glucose, 17.5 mg. per 100 ml.; abundant lymphocytes, scanty Gram-negative bacilli. No penicillin demonstrable in the C.S.F. On 1/2/46 a 4-days course of sulphamerazine was given, starting with a dose of 1 g., followed by 0.5 g. 6-hourly. Since no improvement was noticeable 50,000 units penicillin were given intrathecally for 4 days, starting on 5/2/46. A sample of serum taken on 6/2/46 was positive for agglutinating antibodies against *H. influenzae* type b, giving a marked agglutination up to dilution 1 in 128. From 11/2/46 to 13/2/46 50,000 units penicillin were again given once daily intrathecally, and from 18/2/46 to 4/3/46 the child received 30,000 units penicillin intramuscularly: 3-hourly intervals, with only an occasional rest for 24 hours. In spite of the intensive penicillin treatment, with occasional and subsidiary sulphonamide therapy, the child died on 7/3/46. A total of 3,040,000 units penicillin intramuscularly and 358,500 units intrathecally, of 7.75 g. sulphathiazole, and of 8.5 g. sulphamerazine was given during the course of the illness.

Case 17.—M. H., a girl aged 4 (under the care of Dr. L. Watson, Clayton Hospital, Wakefield), had a history of upper respiratory infection a week before admission on 8/1/46, and three days later she developed stiffness of back and neck, headache, and some vomiting. On examination she was not very ill, and apart from slight neck rigidity there were no other physical signs. At lumbar puncture the pressure was 240 mm.; the C.S.F. was slightly turbid and contained 45 mg. protein per 100 ml., 700 mg. chlorides per 100 ml., numerous polymorphonuclear leucocytes, and a few lymphocytes as well as some Gram-negative bacilli. Culturing gave numerous colonies of *H. influenzae*. A 4-days course of 15,000 units penicillin intramuscularly at 3-hourly intervals was given, and once to be followed by a 2-days course of 1 g. sulphathiazole 6 times daily. On 14/1/46 3-hourly intramuscular injections of 15,000 units penicillin were given for 4 days, and on 17/1/46 the dose was doubled and continued until 25/1/46. On 18/1/46 the C.S.F. was still turbid and contained 50 mg. protein per 100 ml., 730 mg. chlorides per 100 ml., and 2,300 cells per c.mm., of which 80% were polymorphonuclear leucocytes and 20% lymphocytes. Only two colonies of *H. influenzae* were grown. After withdrawal of the C.S.F. 8,500 units penicillin were injected intrathecally. From 25/1/46 to 6/2/46 the dose of intramuscular penicillin was further increased to 50,000 units 3-hourly. On 29/1/46 lumbar puncture was performed again and 8,500 units penicillin injected intrathecally. The C.S.F. contained pus cells but no organisms and no growth was obtained on culture. The fluid contained 0.16 unit of penicillin per ml. It was at this stage that this laboratory was consulted and as none of the previous cultures had been preserved it was impossible to determine the type of the *H. influenzae* by direct methods. A sample of blood serum was obtained, however, and was tested for the presence of agglutinating antibodies. A marked agglutination of a type b strain of *H. influenzae* was obtained to dilution of 1 in 32 and no agglutination with any of the other 5 types. This indirect method of typing made it reasonably certain that the causative organism was of type b *H. influenzae*. Signs of meningeal irritation passed off after a final 4-day administration of sulphamerazine at 6-hourly intervals, beginning on 1/2/46. The patient was discharged on 8/3/46, after having had a normal temperature for 13 days and having been up and about the ward a week before discharge. A total of 8 g. sulphathiazole, 8.5 g. sulphamerazine, 7,280,000 units penicillin intramuscularly and 17,000 units intrathecally had been given.

Case 18.—A. T., a girl aged 2 years 4 months (under the care of Dr. R. L. Langley, Bradford Children's Hospital), fell ill with vomiting on 2/2/46. On 3/2/46 there was some deterioration; she was listless, pallid, vomited copiously, and had a temperature of 101° F. (38.3° C.). The G.P. started to give her 0.25 g. sulphapyridine at 4-hourly intervals on the same day. During the next few days there was no great change and no marked sign in any direction except missing knee-jerks. On 7/2/46 there were slight neck rigidity, convergent strabismus, and a temperature of 100.8° F. (38.2° C.). On admission to hospital on the same day she was semi-comatose, and showed marked strabismus and neck rigidity; Kernig's sign was positive, knee-jerks and abdominal reflexes were absent. Lumbar puncture produced a turbid fluid under high pressure, and 10,000

units penicillin were injected intrathecally after C.S.F. had been withdrawn. On culture the C.S.F. gave a pure growth of *H. influenzae*, which later was shown to belong to Pittman's type b and to be sensitive to penicillin. An attempt to give the child 1.5 g. sulphapyridine 4-hourly had to be abandoned after 48 hours owing to vomiting. Instead 5,000 units penicillin were given 3-hourly. After an initial fall the temperature rose again on 12/2/46, and for 3 days daily intrathecal injections of 5,000 units penicillin were given. The C.S.F. became clear on 17/2/46 and the temperature went down to normal. Intrathecal penicillin therapy was discontinued for 48 hours, but on 16/2/46 the temperature rose to 103° F. (39.4° C.), and the C.S.F. became turbid again. Recourse was had to 12-hourly intrathecal injections of 5,000 units penicillin. In all 8 such injections were given between 16/2/46 and 3/3/46. Intramuscular administration of penicillin was discontinued between 8/2/46 and 3/3/46 in favour of 0.25 g. sulphathiazole 4 times daily. On 26/2/46 the C.S.F. was free from *H. influenzae*, but on 1/3/46 another relapse occurred. A continuous plasma drip was given. The C.S.F. gave good growth of *H. influenzae*, and antibodies against *H. influenzae* type b were found to be present in undiluted serum but not in a dilution of 1 in 10. After starting renewed administration of 5,000 units penicillin intramuscularly at 4-hourly intervals and 5,000 units penicillin 12-hourly intrathecally on 4/3/46 the C.S.F. rapidly became sterile again, and the general condition improved gradually. The patient was discharged well on 14/46. The total dose of penicillin was 365,000 units intramuscularly and 135,000 units intrathecally. In all 3.5 g. sulphapyridine and 15 g. sulphathiazole were given.

Case 19.—P. C., a 7-months-old boy (under the care of Dr. B. A. Evers, Ham Green Hospital, Bristol), had been ill with infection of the respiratory tract, which did not respond to sulphonamide treatment, two weeks before his admission on 6/11/45. There were no symptoms apart from bronchitis and a temperature between 100° F. (37.8° C.) and 102° F. (38.9° C.), and high pulse and respiratory rates. Administration of 30,000 units penicillin daily for 3 days did not improve the general condition. On 22/11/45 signs of meningitis were noticed, and examination of C.S.F. gave the following results: protein, 55 mg. per 100 ml.; globulin, increased; sugar, 6 mg. per 100 ml.; chlorides, 690 mg. per 100 ml.; 176 red cells and 56 white cells per c.mm., mostly polymorphonuclear leucocytes. Some time later the C.S.F. was clear, and the cell count and chloride level suggested tuberculous meningitis. The child died on 4/12/45. Post-mortem examination revealed a purulent meningitis involving the whole of the meninges. A culture taken post mortem was examined in this laboratory and the strain of *H. influenzae* isolated was found to belong to type b. The strain was completely inhibited by 1 unit penicillin per ml. of medium.

Case 20.—A boy, H. D., aged 1 year 8 months. This case has been reported in great detail in an excellent recent paper by Drysdale, McIntosh, and Brodie (1946). The child had a 3-days history of meningitic symptoms before admission to hospital on 18/12/45. The *H. influenzae* strain isolated from the C.S.F. was of Pittman's type b. It was found to be sensitive to 0.7 unit penicillin per ml. of medium and insensitive to sulphapyridine, sulphamezathine, sulphadiazine, sulphathiazole, and sulphamerazine. Until this insensitivity to sulphonamides had been fully established the child had received 5 g. sulphapyridine, 5.5 g. sulphamezathine, and 12.5 g. sulphathiazole in combination with intramuscular and intrathecal injections of penicillin. Sulphonamide treatment was then discontinued and therapy was carried on with daily intramuscular and intrathecal injections of penicillin. In all the child received 10,337,500 units of penicillin intramuscularly and 1,005,000 units intrathecally within 5 weeks. This intensive penicillin treatment led to complete recovery.

Notable features of this case were: (1) The reappearance of *H. influenzae* in the C.S.F. after intrathecal administration of penicillin had been suspended temporarily. (2) The occurrence of severe convulsion 2 hours after the eleventh intralumbar injection of 50,000 units of penicillin. No cerebral irritation had been noticed on the previous 10 occasions, nor had any symptoms occurred after any of the 7 intrathecal injections of 25,000 units which had preceded the higher dose. (3) Careful penicillin assay in the C.S.F. revealed that with daily intrathecal doses of 50,000 units an average concentration of 1.7 units penicillin per ml. of C.S.F. could be maintained, while with a daily dose of 25,000 units the concentration averaged only 0.6 unit per ml.

Discussion

The first point emerging from this survey is that 20 cases of *H. influenzae* meningitis in children, of which 19 were caused by Pittman's type b, could be collected in a small area within a period of just under two years. It would seem, therefore, that at present the condition is not as rare as the scarcity of case reports in this country would suggest. The second point is the varied nature of the symptoms with which an infection of the meninges with *H. influenzae* may manifest itself. Every

type of meningitis, from the fulminant infection leading to death in 24 to 48 hours to the protracted case typical of tuberculous meningitis, may be met with. In addition difficulties arise in diagnosing meningitis in children under 7 to 8 months of age owing to absence of the usual symptoms of meningitis, and the consequent delay in treatment is responsible for the high case fatality rate in this age group (Alexander, 1943b). Thus it is seen that in this series both the children under 1 year of age (Cases 4 and 19) died, the latter having no symptoms for a considerable time. In view of the protean nature of the symptoms of *H. influenzae* meningitis it is fortunate that the sulphonamides most effective against *H. influenzae*—i.e., sulphadiazine and sulphamezathine—have equally good bacteriostatic properties against most other organisms causing meningitis except the tubercle bacillus. Sulphadiazine and sulphamezathine should be the drugs of choice, therefore, in every case of meningitis, and particularly in children, as soon as a clinical diagnosis is made and C.S.F. has been withdrawn for culture, without waiting for bacteriological confirmation. Simultaneously penicillin should be given, since its bacteriostatic effect on a large number of strains of *H. influenzae* has now been well established. Penicillin sensitivity of *H. influenzae* strains varies to some extent, however, and determination of the sensitivity of any particular strain should be a guide to the concentration of penicillin in the C.S.F. to be aimed at (M. Gordon and Zinnemann, 1945). Penicillin should be administered both systemically and intrathecally to maintain the requisite concentrations in blood and C.S.F. As Alexander (1943b) suggests daily lumbar puncture as an essential part of treatment, the intrathecal injections cause little if any extra burden to the patient. The systemic administration also deals adequately with any possible septicaemia, which is a common accompaniment of the meningitis (Fothergill, 1937)—as Case 7 illustrates. The administration of type b specific *H. influenzae* rabbit antiserum is also indicated if the causative organism is of the b type.

It is necessary to stress the need for continuing medication without interruption until 7 days after the C.S.F. has first become sterile. Cases 1, 2, 4, 11, 14, 18, and 20 illustrate the dangers of suspending treatment too soon after the C.S.F. has become clear. Moreover, there is also the theoretical risk of producing penicillin-resistant strains of *H. influenzae* if the concentration is not maintained until the C.S.F. has remained sterile.

Under the conditions of the survey it was impossible to trace the sources of infection. Alexander (1943a) produced evidence that typable *H. influenzae* strains are harboured in the nasopharynx of children. Straker (1945) confirmed this in a number of children in this country. It is interesting in this connexion to note that in six cases of this series—namely, Nos. 5, 11, 13, 14, 17, and 19—a respiratory infection preceded the onset of meningitis. Possibly, comparative studies in adults and children might contribute to answer the question why *H. influenzae* meningitis is predominantly a disease of childhood.

The fairly wide differences as to choice and dosage of sulphonamides used should be eliminated if the American suggestions are followed (Alexander and Leidy, 1943), though the task remains of determining more accurately the dosage and route of administration of penicillin. Cases 15 and 17 recovered with comparatively small intrathecal doses—the first with 10,000 units administered daily for 4 days, and the second with 8,500 units given intermittently. In Case 20 Drysdale, McIntosh, and Brodie found, however, that 50,000 units intrathecally were required to maintain a concentration of approximately 2 units per ml. at the end of 24 hours, while 25,000 units gave a concentration of only 0.6 unit per ml. of C.S.F. Their results give a lead as to the dosage to be employed intrathecally, considering that the majority of *H. influenzae* type b strains are inhibited by approximately 2 units per ml. In view of possible cerebral reactions to such high intrathecal doses it may be worth while to give the daily dose of 50,000 units in two 12-hourly administrations. A reduction of the daily dose may be the result of such a procedure, as Case 18 suggests, in which complete recovery was the result of thirty 12-hourly intrathecal injections of 5,000 units of penicillin supported by 0.25 g. sulphathiazole 6-hourly.

In Cases 8, 11, 12, and 13 death occurred through internal hydrocephalus, probably due to adhesion or to clots in the C.S.F. Alexander (1944) suggested that this complication might

be overcome by introduction of air and heparin into the cerebrospinal canal, and it may be worth while to try her methods in such desperate cases. It need not be feared that children thus saved might prove to be crippled in one way or another for the rest of their lives. Regarding such consequences Alexander (private communication) states:

"The experience in this country when both sulphadiazine and type-specific rabbit antiserum are used in combination for the treatment of influenza meningitis indicates that any residual damage to the brain is exceedingly rare following recovery. This appears to be true even in very chronic cases of the disease which recover over a long period of time. For example, I know, as a result of my own experience and by talking over the experiences of a number of others, of only one case in which residual damage to the brain followed a child's recovery."

In all, 5 out of 20 cases were treated with sulphonamides alone. Only one of these five recovered. Fifteen cases had combined sulphonamide-penicillin treatment and eight of them recovered. The total number of cases is too small and the methods of treatment varied too much to allow of statistical assessment. The only conclusion to be drawn is that the encouraging recovery rate suggests pushing to the limit the combined sulphonamide-penicillin treatment, perhaps supported by specific antiserum.

The sporadic occurrence of *H. influenzae* meningitis in this country makes it very difficult for any investigator, single-handed, to work out a satisfactory routine treatment. It seems reasonable to suggest that cases of *H. influenzae* meningitis of the non-fulminant type should be concentrated in a number of treatment centres. An adequate method of treatment, as in the case of subacute bacterial endocarditis, might be evolved for the majority of cases, and a substantial number of children's lives might thus be saved.

Summary

A survey of the various methods of treating *H. influenzae* meningitis is presented.

Clinical data are given of 19 cases of *H. influenzae* type b meningitis and of 1 case due to *H. influenzae* of the respiratory group. Of 5 cases treated only with sulphonamides, one recovered. Fifteen cases had combined sulphonamide-penicillin treatment. Eight of these recovered. It is suggested that the combined administration of these drugs should be used more energetically in *H. influenzae* meningitis. In view of the good therapeutic results reported from the U.S.A. specific *H. influenzae* type b rabbit antiserum, which is now available in this country, should also be given.

The establishment of a number of treatment centres to evolve a standard routine method of treatment is advocated.

This survey would not have been possible without the kind co-operation and permission to use clinical data of Prof. J. C. Spence, Prof. J. W. Tulloch, Prof. W. C. Vining, Mr. D. W. C. Northfield, and Drs. J. Allan, G. W. Anderson, K. M. D. Bailey, M. I. Bery, K. E. Cooper, J. M. Croll, C. F. Drysdale, J. S. Faulds, F. W. Gunz, M. J. Lawson, D. G. McIntosh, D. L. McQuillan, A. I. Messer, B. Morrison, J. O'Connor, J. W. Orr, B. A. Peters, T. M. Pole, K. B. Rogers, E. Rosenblum, L. Watson, and C. J. Young. I have very much pleasure in expressing my indebtedness for the help thus given. Acknowledgments are also due to Prof. J. W. McLeod and Dr. J. Gordon for supplying me with some of the strains of *H. influenzae* for typing, and to Dr. M. Gordon for valuable suggestions during the preparation of the MS.

INFECTIONS OF THE NERVOUS SYSTEM OCCURRING DURING AN EPIDEMIC OF INFLUENZA B

BY

A. D. LEIGH, M.R.C.P.

First Assistant, Department of Neurology, London Hospital

Influenza epidemics in the past have on occasion been associated with cases presenting evidence of cerebral or cerebrospinal infection, although the relationship is obscure. During the epidemic of influenza B at the beginning of 1946 nine cases of acute infection of the nervous system, occurring at three separate levels, were observed. Two of these presented signs of brain-stem encephalitis, two of myelitis, and five of generalized polyneuritis akin to the acute toxic polyneuritis of Guillain, Barré, and Strohl (1916).

Brain-stem Group

Case 1.—A girl aged 18 complained of diplopia and right-sided ptosis. She was well until May 14, 1946, when she developed generalized headache and extreme lassitude. She had intense sleepiness, and found it difficult to remain awake. Her neck felt a little stiff. She was bad-tempered, and had one outburst of unreasonable rage. Three days before the onset of her symptoms she had been in close contact with a girl who had a severe attack of influenza. On the 18th her vision became blurred, and she noticed diplopia in all directions. Next day the right lid began to droop, and she experienced discomfort in the right supraorbital region. The headache persisted; there was no polyuria or polydipsia; the appetite was poor; and she still felt very sleepy. She had had diarrhoea of and on for the past nine to ten days. On May 24 she was admitted to the London Hospital under the care of Dr. Russell Brain.

Examination showed the following: Right pupil a little larger and reacting a trifle more sluggishly to light than the left; equal brisk reaction to accommodation; right ptosis; weakness of elevation, adduction, and depression of the right globe; diplopia in all directions; all tendon reflexes depressed; knee-jerks obtained only on reinforcement; equivocal right plantar response. Lumbar puncture on May 25: C.S.F. pressure, 100 mm.; 8 cells, mainly lymphocytes; protein, 20 mg. per 100 ml.; W.R. negative; Lange, 222321000. On the 28th the white cell count was 6,700 per c.mm. (polymorphs 70%, lymphocytes 25.5%, large hyalines 4.5%). June 6: No diplopia; right ptosis; very slight weakness of elevation of right globe; pupils equal, reacting sluggishly to light. On the 8th there were full ocular movements and no diplopia. The tendon reflexes were sluggish and plantar responses flexor. The patient was discharged symptom-free.

Case 2.—A medical man aged 38 complained of headache, photophobia, diplopia, dizziness, and tingling in hands of five days duration. On March 12, 1946, he had a sore throat, cough, and general malaise, but after sulphathiazole for three days he felt fit. About March 26 he developed dizziness and photophobia, followed 24 hours later by tingling in both hands and difficulty in focusing. On the 30th he had diplopia in all directions. The left pupil was larger than the right, and both pupils reacted only sluggishly to light. Next day there was an increase in the severity of all symptoms: tingling now present in feet; headaches more severe, mainly frontal aching pain; movement of eyes painful; diplopia in all directions except to the extreme right. Left ptosis was noticed by the patient on April 1. He felt extremely drowsy, and slept eleven to twelve hours. He was admitted to the London Hospital under the care of Dr. Clifford Wilson. The patient presented a difficult diagnostic problem, as he had suffered from Hand-Schüller-Christian disease since 1932 and had had five injections of "pitressin" daily to control his diabetes insipidus.

He was seen by Dr. George Riddoch on April 2. Examination showed: Pupils moderately dilated, regular, left larger than right; very feeble reaction to light and, on convergence, right more than left; gross paresis of all external ocular movements, left more than right; severe bilateral ptosis. Upper limbs: no weakness, ataxia, or dystonia; tendon reflexes absent. Lower limbs: no weakness, ataxia, or dystonia; knee-jerks just present; ankle-jerks absent; plantar reflexes flexor. There was no cutaneous sensory change. The abdominal reflexes were present and equal. B.P. 190/120. Urine normal. Lumbar puncture: pressure 240 mm.; 4 cells; protein, 30 mg. per 100 ml.; Lange 1222100000; W.R. negative. A radiograph of the skull showed nothing abnormal. The patient was considered to be suffering from an acute infection of the nervous system chiefly affecting the brain-stem. Daily injections of 2 ml. of "hepolon" were advised. On April 3 the left pupil was larger than the right, both fixed to light; sluggish reaction to accommodation; ptosis more severe, left worse than right. The white cell count was 7,250 per c.mm. (polymorphs 69%, lymphocytes 25%, eosinophils

5%, large hyalines 3.5%). On the 5th there were almost complete phthalmooplegia interna and externa; dilated fixed pupils; sensory pangle to cotton-wool and pin-prick below mid-forearm; vibration loss below the clavicles, and he still had marked photophobia. He was seen on the 8th by Dr. Russell Brain, who confirmed the above signs and noted, in addition, weakness of the hip muscles. Signs of recovery in the eyes were observed on the 12th—a little movement of the lids and some pupillary response to light. Vibration sense started to return in right leg on the 15th. On May 7 convergence was returning, the pupils reacted well to light, and the external recti were still weak. On June 1 he still had diplopia in all directions, except on looking upwards and to the right. The right pupil was a little larger than the left, both reacted sluggishly to light and briskly on accommodation. Left eye: defective elevation, abduction, and adduction. Right eye: defective elevation and adduction. He still had slight weakness of dorsiflexion of wrist and fingers, complete areflexia of upper and lower limbs, and weakness of hip flexors, abductors, and adductors. Plantar responses were flexor, and there was no sensory change.

Myelitic Group

Case 3.—A man aged 24 had an attack of influenza on Jan. 4, 1946, with fever, sweating, running nose, and sneezing, but he had no headache or sore throat. A slight cough and aching pain in the frontal region began on Jan. 7, and he was in bed for seven days. At the end of this time both lower limbs were stiff, the right more than the left, and the right lower limb felt numb. There was a little delay in initiating micturition. Past history: Pott's disease from 2 to 9 years of age; tuberculous left knee-joint, with eventual removal of patella, arthrodesis, and osteotomy; well since 1939. His father died of phthisis in 1929. The patient was admitted to the London Hospital under the care of Dr. George Riddoch on Feb. 1.

Examination on the 4th revealed a gibbus, D.7-D.8. C.N.S.: nil abnormal in cranial nerves and upper limbs; left lower limb—gross shortening, arthrodesis at knee, patella absent; bilateral lower-limb spasticity, right greater than left; lower abdominal reflexes absent; right knee-jerk and both ankle-jerks increased; left knee-jerk absent; bilateral extensor plantar responses; vibration sense impaired in both lower limbs; postural sensibility impaired in toes; waxy diminution to pin-prick and cotton-wool below D.6. Lumbar puncture on Feb. 11: pressure 80 mm.; no block; 2 cells; protein, 20 mg. per 100 ml.; W.R. negative; Lange 1121110000. A radiograph of the spine showed old tuberculous kyphosis but no sign of activity. During the following month the power of both lower limbs improved and the sensory changes regressed. On June 4 the lower-limb weakness had improved. There was moderate bilateral spasticity with loss of tickle sensation over the inner aspect of the right knee, relative analgesia below the right knee, and impaired vibratory sense in both feet. Sensory level to dragged pin at D.10.

Case 4.—A married woman aged 29 began to have backache, headache, and muscular aching in mid-February, 1946. Influenza was diagnosed, and she was kept in bed for seven days. On getting up she noticed weakness of both lower limbs and tingling in the toes, which persisted until the time of examination. There was occasional urgency of micturition. Examination on May 1 revealed nothing abnormal in the cranial nerves or upper limbs. There was moderate bilateral spastic weakness of both lower limbs, with extensor plantar responses. There was no sensory change and the abdominal reflexes were absent. On May 29 she was much improved symptomatically—the lower limbs were stronger, but the signs persisted unchanged.

Polynuritic Group

Case 5.—A married woman aged 46 had lassitude and anorexia in mid-December, 1945. On Jan. 24, 1946, she had slight sore throat, pyrexia of 101° F. (38.3° C.), and aching in the lumbar region. The pyrexia continued for 25 days, and on Feb. 17 was followed by photophobia and left facial weakness, which rapidly spread to the right side of the face. At this time she noticed paraesthesia in the left thumb. She was admitted to the London Hospital under the care of Dr. George Riddoch on Feb. 21. The temperature was 98° F. (36.7° C.), pulse 80. She had complete facial diplegia, with loss of taste. There was no other nervous abnormality. Lumbar puncture: pressure 70 mm.; no excess of cells; protein, 120 mg. per 100 ml.; W.R. negative. Next day a blood count showed: Hb, 88%; W.B.C., 7,600 (polymorphs 45%, lymphocytes 48%, basophils 2.5%, large hyalines 5%). On the 23rd she had paraesthesiae along the ulnar border of the left forearm and hand; the left lower limb felt weak; both ankle-jerks were sluggish; and vibration sense was a little impaired in the left big toe. Two days later the frontalis was working—on the left side more than the right. On the 27th all facial muscles responded to faradism. She was treated by galvanism to the face and given 2 ml. of "hepolon," intramuscularly, twice weekly. The signs were unchanged on March 11.

Case 6.—A married woman aged 54 had diarrhoea on March 13, 1946; this lasted for seven days. Her daughter also suffered from

this complaint. The patient was admitted to Haymeads Hospital under the care of Dr. Leiper on the 20th, complaining of backache and vomiting. There were no abnormal physical signs in any system apart from a blood pressure of 200/110. All tendon reflexes were present. Dimness of vision started on the 27th, beginning with a left homonymous defect and progressing within 24 hours to complete blindness. She became drowsy and confused; the left optic disk was blurred; the tendon reflexes were absent, and the plantar responses flexor. Lumbar puncture: pressure 300 mm.; no increase in cells, protein, 288 mg. per 100 ml.; W.R. negative. After a few days the vision began to improve, and she was found to have a left lower homonymous quadrantic field defect. Plantar responses were flexor. She was seen by Dr. Russell Brain on July 3. The blood pressure was 210/95. The disks and fundi were normal. There was no field defect or any abnormality in the cranial nerves. Upper limbs: power good, no dystonia or ataxia; tendon reflexes present and equal; no sensory change to pin-prick, cotton-wool, vibration, or posture. Lower limbs: power good, no dystonia or ataxia; knee- and ankle-jerks absent on reinforcement; plantar responses flexor; no sensory change to pin-prick, cotton-wool, posture, or vibration. Abdominal reflexes present and equal.

Case 7.—This patient, a man aged 46, developed a cough during the first week of March, 1946. There was no pyrexia or sore throat, but he felt tired and ill. A fortnight later he noticed weakness of the lower limbs, which gradually increased, and three days later it involved the hands. Within a week he was unable to walk more than 400 yards or to shave. On April 1 he was admitted to the London Hospital under the care of Dr. George Riddoch.

Examination revealed no abnormalities in the cranial nerves. There was weakness of the whole of the upper limbs, most marked distally, and in the flexors and extensors of the wrist and fingers. The tendon reflexes were depressed. In the lower limbs the power was good in all groups save the dorsi- and plantar-flexors, especially the former. The knee-jerks were sluggish and the ankle-jerks much diminished. There was no sensory change to pin-prick, cotton-wool, posture, or vibration in upper or lower limbs. The abdominal and intercostal muscles were strong. The abdominal reflexes were present. Lumbar puncture on April 6: pressure, 200 mm.; cells less than 1; protein, 20 mg. per 100 ml.; W.R. negative. He was given 2 ml. of "hepolon," intramuscularly, on alternate days, and he slowly recovered. On May 20 the power was greatly improved and he walked unaided.

Case 8.—A Wren aged 19 had a very mild cold early in December, 1945, which lasted for a week. On Dec. 22 she noticed weakness of both shoulders and weakness of flexion of arms on shoulders, which progressed until Jan. 2, 1946. She remained on duty, but on Jan. 12 she had weakness at the hips, and this increased during the next three weeks until she was unable to stand. There were no other symptoms. She was admitted to the London Hospital under the care of Dr. George Riddoch on Feb. 18.

Examination revealed no abnormality of the cranial nerves. There was considerable weakness of all muscles, particularly of the shoulder-girdle muscles. The triceps and the brachioradialis were weaker on the right than on the left. There was slight weakness of the muscles of the forearms and hands, the intercostal and abdominal muscles, the extensors of the trunk, and all hip-girdle muscles, especially the flexors. The flexors and extensors of the knees were somewhat impaired, but the leg and foot muscles were good except for weakness of dorsiflexion on the right due to old peroneal-nerve injury. The abdominal reflexes were brisk and equal. All tendon reflexes were present and equal. There were bilateral flexor plantar responses. No sensory abnormality was noted. Lumbar puncture on Feb. 23: pressure 60 mm.; 1 cell; protein, 20 mg. per 100 ml.; Lange 0111000000; W.R. negative. During the next eight weeks the left lower lobe of the lung collapsed and she had to be placed in a Drinker respirator. Plugs of mucus were sucked out on two occasions, with eventual re-expansion of the lung. Her neurological condition, which had been slowly improving, relapsed as the result of the pulmonary complication. On June 6 she was transferred to another hospital for swimming-bath treatment. She was then as weak as when first seen.

Case 9.—A married woman aged 54 developed a sore throat, cough with greenish sputum, and pyrexia at the end of January, 1946. Three days later the temperature rose to 104° F. (40° C.), the sputum increased, and bronchopneumonia was diagnosed. Sulphathiazole and systemic penicillin were given. On Feb. 16 she was afebrile; rales were heard at both bases. On the 22nd she had weakness in both shoulders, which increased during the following 24 hours. Next day she had tingling in the finger-tips, and the lower limbs felt weak. On the 25th she was seen by Dr. George Riddoch. Moist sounds were heard at both bases. The cranial nerves were normal. There was weakness of all the upper-limb muscles, especially the scapular group, the deltoid, the flexors of the elbow, and, to a less extent, the extensors of the wrists. The supinators were more affected than the pronators, and the extensors of wrist and fingers more than the flexors. There was no weakness of the trunk, but moderate weakness of hip flexors and adductors of thighs was noted. The dorsiflexors

of the feet and toes were weak. Good power remained in the lower-limb muscles. Tendon reflexes were absent in the upper and lower limbs, save a much diminished left knee-jerk. Plantar responses were flexor. Abdominal reflexes were present and equal. There was no sensory change in the upper limbs; vibration was absent in the feet. On March 7 moist sounds were still heard at both bases. The physical signs in the central nervous system were unchanged, apart from diminution to pin-prick below the elbows and mid-calf. The patient was given 2 ml. of "hepolon," intramuscularly, daily. There was increased power in the affected muscles on March 23, and considerable improvement in the power of all affected muscle groups on May 2. The knee-jerks were just present.

Discussion

The brain-stem group is remarkably reminiscent of encephalitis lethargica, although it differs greatly from the haemorrhagic influenzal encephalitis first described by Leichtenstern (1890). Drowsiness, with the rapid development of nuclear midbrain lesions, occurred in both cases. The fleeting abnormal plantar responses in one patient and the weakness of proximal muscles groups, with areflexia and peripheral sensory change, in the other indicate a more widespread attack on the neuraxis. Complete recovery ensued within three weeks in Case 1; and equally striking, although slower, was the improvement in Case 2, following a total ophthalmoplegia interna and externa. Unfortunately, it is a matter for speculation whether the condition can be identified with encephalitis lethargica. Von Economo (1931) considers that the somnolent-ophthalmoplegic type is the true basic form of this disease, and is the type that occurs sporadically. Certainly Case 1 might be regarded as a classical example of this variety.

Signs of a transverse or patchy myelitis affecting the lower thoracic cord occurred in two patients after an influenza-like illness. Recovery was slow, and, again, in the absence of pathological material, it can only be suggested that this group corresponds to the two patients described by Greenfield (1930), in whom histological examination disclosed evidence of an acute disseminated encephalomyelitis.

Of the polyneuritic group, Case 5 conforms to the classical type of acute toxic polyneuritis of Guillain, Barré, and Strohl (1916)—a febrile illness for three weeks being followed by facial diplegia, with an increase in the protein content of the cerebrospinal fluid. In Case 6 the patient, after an attack of diarrhoea, became drowsy and confused, with rapid visual failure of a cerebral type. All tendon reflexes disappeared, and the C.S.F. contained 288 mg. of protein per 100 ml., with no increase in cells. During recovery, which occurred rapidly and completely, a homonymous quadrantic field defect was observed. The tendon reflexes in her lower limbs were still absent three and a half months after the onset of symptoms. Case 7 developed a subacute weakness of the dorsiflexors of the wrists and ankles, without sensory change and with a normal C.S.F., three weeks after the onset of symptoms. Case 8 was in every way similar, a slowly progressive weakness of hip- and shoulder-girdle muscles developing over six weeks and then becoming stationary, with no sensory change and a normal C.S.F., two months after the onset of symptoms. In Case 9 weakness of hip- and shoulder-girdle muscles developed following a 23-day pyrexia, associated with a basal bronchopneumonia. Recovery occurred slowly over the two months she was observed.

This small epidemic of nervous diseases, while of such varied types, appears to be related to some common factor. Whether the prodromal illness was in fact an attack of influenza B is unknown, but the incidence of the cases is related to the peak period of this 1946 epidemic. Certainly, too, it seems that the type of case described above has been unusual during the past few years, as have epidemics of influenza B, sporadic cases of which appeared in England for the first time in 1939. In 1943 only a minor outbreak occurred, but in 1946 the death rate from influenza rose to a higher level than for the two previous years.

Whatever the relationship, however, the three groups seem to be the result of a virus attack on the nervous system, producing either poliomyelitis or myelocystitis. It would appear likely from the known characteristics of the viruses which attack the nervous system that two separate viruses are thus concerned.

Summary

A small epidemic of nervous diseases coinciding with an epidemic of influenza B is described.

It is suggested that a myelinoclastic virus and a poliomyelitic virus are concerned.

My thanks are due to Dr. George Riddoch and Dr. W. Russell Brain for their criticism and advice.

ALLERGIC REACTIONS TO PENICILLIN

BY

A. I. SUCHECKI, M.D. Paris
(From St. Charles' Hospital, L.C.C.)

Reports on allergic reactions to penicillin are increasing in number. This is becoming an important problem as more and more patients are receiving penicillin therapy. Evidence is accumulating that the offending agent is the active principle of penicillin. Theoretically, therefore—and actual practice has shown this to be true—reactions may arise with any commercial preparation of the drug. The route of administration has in the majority of cases a bearing on the clinical features and site of the allergic reaction. Local use of penicillin will give rise predominantly to contact or sensitization dermatitis, while parenteral administration is more likely to produce immediate or delayed reactions resembling anaphylaxis.

Review of the Literature

Pyle and Rattner (1944) and Kolodny and Denhoff (1946) reported cases with skin lesions due to penicillin sensitivity. The latter found among dermatological patients treated with parenteral and local penicillin a 25% rate of skin complications as compared with 6% among non-dermatological patients. Especially in cases of fungous infection was contact dermatitis liable to develop, and skin tests were positive to penicillin and to trichophyton. From the study of their cases they concluded that there is no clear-cut relationship between the antigenic substances common to some of the pathogenic fungi (Hyphomycetes) and antigens of *Penicillium notatum* (Ascomycetes), but clinical observations are suggestive. Goldman *et al.* (1946) found 16 instances of contact dermatitis among 350 cases treated with penicillin locally. Vickers (1946) described a case of penicillin sensitization dermatitis; a patch test with penicillin solution was strongly positive. Hellier (1946) stressed the rarity of contact dermatitis due to penicillin as compared with that due to sulphonamides.

More characteristic are the manifestations described since 1943; they are practically always due to intramuscular penicillin and resemble severe urticaria or serum sickness. Lyons (1943), when reporting on penicillin therapy of surgical infections in the U.S. Army, found that there were urticarial reactions not attributable to particular batches of the drug. Of 209 cases 12 (5.7%) had an urticarial reaction, of which he described three types: (a) without fever; (b) with fever to 101° F. (38.3° C.); (c) with fever to 103° F. (39.4° C.) and abdominal cramps. The urticaria appeared as early as the first day or as late as the fourth week. Fever was present only if urticaria was severe, and normally did not exceed 101° F. Skin tests were negative. No precipitins were found in the serum of patients tested during the phase of urticaria, and heterophil agglutinins were not significantly and constantly increased. Crip (1944) reported a case in which a massive generalized urticaria appeared on resumption of a second parenteral course of penicillin. This persisted for six days. He made special laboratory investigations which showed the presence of some immune substances (reagins and precipitins) in the patient's serum. According to Crip the following takes place: First penicillin administration—drug discontinued—second penicillin administration → allergic reaction.

Strazza (1946) had a case of a man aged 23 who six days after a course of parenteral penicillin became very ill, with urticaria, pruritus, restlessness, insomnia, pain in the hands and feet, breathlessness, and oedema of pharynx with dysphagia. He recovered after eight days. Calcium gluconate intravenously was ineffective, and a scratch test was negative. The paper on penicillin allergy by Kolodny and Denhoff (1946) gives, among others, data concerning six cases with urticaria and five cases with a serum-sickness type of reaction. This classification is arbitrary, but clinically useful as it permits the separation of mild from severer reactions. In seven patients the reaction started fourteen days after beginning penicillin therapy; in another it began twenty-three days after. Five patients had swelling of small joints of the extremities, oedema of face, moderate lymphadenopathy, generalized arthralgia, myalgia, and malaise. Recovery was complete in four or five days. Adrenaline gave prompt but transient relief. Haswell and Wilkinson (1946) have written an interesting account of four cases presenting a reaction similar to serum sickness; all the patients gave a history of previous treatment with local penicillin. The reaction occurred from six to twelve days after starting intramuscular injections of penicillin. Skin tests were negative.

Gordon (1946) reviewed the literature on the problem of allergy due to penicillin and added three of his own cases. According to this author the incidence of allergic reaction during the course of treatment is not frequent. A delayed serum-sickness type of reaction occurs even more uncommonly—possibly once in 1,500 or 2,000 cases. Gordon's personal cases developed the reaction from two to seven days after cessation of penicillin therapy. The first manifestation in each was an intense urticaria with severe pruritus. Weal formation spread all over the body, and in two out of three oedema of the eyelids occurred. Pain in the joints was noticed; malaise, mild fever, and tachycardia were also present. Both palms presented an exfoliative dermatitis in the later stages of the reaction. Treatment with adrenaline gave satisfactory results, but its effect was transitory. The patients recovered in seven to ten days.

Below are given a list of authors and the number of their published cases. The list includes Barker, Morris and Downing, Sullens, and Macey and Hays, as quoted in Gordon's paper. With my own nine cases the total of collected case histories amounts to forty seven.

	No. of Cases
Lyons (1943)	12
Criep (1944)	1
Barker (1945)	1
Morris and Downing (1945)	1
Sullens (1945)	1
Macey and Hays (1945)	3
Haswell and Wilkinson (1946)	4
Gordon (1946)	3
Strazza (1946)	1
Kolodny and Denhoff (1946)	11
Total	38

They can be classed as (a) allergic hydrarthrosis; (b) urticaria; (c) simulating serum sickness; (d) anaphylactic-shock-like syndrome. Cases of sensitization dermatitis are included. A summary of the clinical features, with a few illustrative cases, follows.

Allergic Hydrarthrosis

I could find no similar published cases. As already noted, swelling of the small joints with arthralgia is a common finding, but isolated articular involvement of a large joint is rare. Four such cases have been seen. They were all similar in their onset, duration, symptomatology, and benign character, and none of the patients had a history of previous penicillin therapy. Three had been treated for syphilis (two with primary syphilis and one with syphilitic arteritis) and one for multiple lung abscesses. The joint swelling occurred two to five days after starting penicillin; the joint involved in all cases was the right knee. Undoubtedly this was pure coincidence, and I am expecting in the future to find other large joints affected. The knee became swollen and slightly tender, and gradually a large effusion developed. There were no signs of inflammation and the general condition remained unaffected; the temperature was not raised, and the small joints were not involved. No

skin eruption was noticed. Penicillin injections were not discontinued on account of this complication, as it was felt that this was not serious enough to warrant such a drastic step. The effusion gradually lessened, and the joint became normal in eight to ten days. Only symptomatic treatment was given.

Illustrative Case

Case 1.—Male aged 42 years. He had never had penicillin before. He was admitted to St. Charles' Hospital on Aug. 26, 1946, suffering from cerebral thrombosis of syphilitic origin. On the 31st penicillin was started in doses of 50,000 units intramuscularly every three hours. The drug used was a commercial batch of the sodium salt in aqueous solution. On Sept. 5 it was noticed that the right knee was oedematous. It was tender to palpation and fluid was present, but the skin was not hot, shiny, or red. An x-ray photograph taken on the same day showed no bone injury. The hydrarthrosis remained for about ten days and then slowly subsided. Eventually the joint returned to its former healthy state. Penicillin therapy was not stopped till the full dosage was given (5,000,000 units). Treatment was symptomatic and there was no recurrence.

Urticaria

This is a mild form of reaction, also called "immediate" by some authors to differentiate it from the delayed reaction of serum-sickness type. In reality the time of occurrence of both is extremely variable. In one case that I studied the onset of a mild urticaria was delayed for several days after cessation of penicillin, while in another a severe serum-sickness-like reaction made its appearance very early during treatment. The only basis for differentiation lies in the clinical features. Urticaria is mild, transient, and often overlooked, while the severe form of serum sickness has a dramatic onset with constitutional disturbance, often pyrexia, and occasionally collapse. This form needs prompt recognition and appropriate treatment.

The urticaria appears most commonly during penicillin treatment, as does the previously described knee effusion. Only the skin is involved, and the principal lesion consists of a blotchy rash against an erythematous background. The small weals are distributed on the trunk—usually the front of the chest and upper abdomen. Limbs, neck, and scalp may also be affected. Pruritus is always present, and this is the first thing the patient notices. The temperature remains normal and there is no tachycardia. In one only of my cases was there a history of previous penicillin administration.

Illustrative Cases

Case 2.—Soldier aged 23, with a diagnosis of post-basal empyema following pneumonia. He had been treated in December, 1945, with intramuscular injections of penicillin. Admitted to St. Charles' Hospital on March 25, 1946. Penicillin in three-hourly doses of 30,000 units was given from April 2 to 16. On the third day after starting injections the patient complained of itching on the chest and abdomen. A mild urticarial eruption was noted and calamine lotion applied locally. Penicillin was continued and no more notice was taken of the urticaria, which faded out after four to five days. I cannot find in the records any mention of a reaction during the first course of penicillin.

Case 3.—A young doctor aged 30, admitted to St. Charles' Hospital for recurrent boils of neck. He had never had penicillin previously. In July, 1946, was started a course of three-hourly intramuscular injections of sodium penicillin for five days; each injection consisted of 30,000 units. Three days after completion of treatment a mild urticarial rash appeared on scalp, neck, and legs. Intense irritation of the skin and moderate nocturnal dyspnoea were present. Intravenous calcium gluconate 10% solution gave no relief. Recovery took place in five to seven days.

Reaction Simulating Serum Sickness

This reaction is not confined only to the skin, but produces in addition an oedema which at times is considerable, arthralgia, bronchospasm, and a severe general reaction. It may occur during penicillin treatment or several days after cessation. On the average the onset is from five to thirteen days after the first injection. In two of my cases penicillin has been given before, and in both a penicillin patch test was positive.

The onset is rather abrupt, with at times fever of 102° F. (38.9° C.). Giant urticaria affects the skin all over the body. Within twenty-four hours the weal formation is completed; even the face is not spared. The skin irritation is intense, and the patient becomes restless and cannot sleep. Angioneurotic oedema is always present in these cases. Particularly noticeable

is the oedema of face, lips, and eyelids. The hands, feet, and forearms are swollen and painful. The oedema is intense, and is a classic example of pitting oedema. One has only to consider this aspect of the reaction to realize how widespread and intense is the damage to the capillaries; fortunately it is transient and recovery is complete. The urine is clear and contains no albumin. Blood pressure remains within normal limits. In one subject only have I noticed subcutaneous bruising of the palms of both hands, and he complained of tenderness and aching in the affected palms. No exfoliative dermatitis was noted in any of my cases. Arthralgia is not the rule. Usually the small joints of hands and feet are involved.

Illustrative Cases

Case 4.—Male aged 27 years, with no personal history of asthma, urticarial rashes, or migraine. He was treated at St. Charles' Hospital for a septic right index finger, and had 700,000 units of sodium penicillin between Sept. 4 and 8, 1946. At that time no complications had been noted and the patient was discharged. On Sept. 17—i.e., nine days after completing the course of penicillin—he became ill with a temperature of 102° F. (38.9° C.) and generalized urticaria. He was admitted again on the 20th. On examination giant weals were seen on neck, chest, abdomen, and thighs. The areas of skin between the weals were erythematous and slightly raised. The palms showed diffused ecchymotic subcutaneous patches. Severe angioneurotic oedema of feet, legs, dorsum of hands, wrists, face, lips, and left upper eyelid was present, and pitting oedema round ankles and dorsum of feet. The patient complained of intense irritation of the skin and tenseness in both hands. His general condition was poor and he was restless. The heart and lungs were normal, as were also the blood pressure and urine. He was put on strict bed rest, hypodermic injections of adrenaline, ephedrine, and phenobarbitone, with calamine lotion locally. The urticaria cleared after three days. The oedema persisted for a few more days and he was allowed up on Sept. 27. He went home on Oct. 1.

Case 5.—Male aged 23 years. This patient had gonorrhoea in May, 1946, and was treated with 150,000 units of penicillin. He contracted syphilis in the following August. He attended a V.D. clinic for treatment and was put on two daily injections of 120,000 units of penicillin in ethyl oleate. After the tenth injection he developed a giant urticaria, and was admitted to St. Charles' Hospital, complaining of severe pruritus, oedema of lips, and malaise. In view of the seriousness of the general reaction penicillin had to be discontinued. The reaction gradually subsided on adrenaline and phenobarbitone. A penicillin patch test was strongly positive. Calcium gluconate 10% solution given intravenously for four days brought no improvement. He was discharged on Sept. 14.

Case 6.—Male aged 26 years, suffering from a discharging sinus of the left shoulder following gunshot wounds. He gave the following history of previous penicillin treatment and allergic reactions: (1) July, 1944, given nearly 2,000,000 units (make unknown) by intramuscular injections. Developed an urticarial rash during treatment; no details supplied. (2) August, 1945, received intramuscular injections of sodium penicillin for 48 hours (total of 270,000 units). Three days later, while at home, urticaria developed. The patient could give no details of its duration or severity.

On July 25, 1946, this patient underwent an operation for chipping of the humerus at St. Charles' Hospital. On the same day three-hourly parenteral penicillin was started, and this was discontinued on Aug. 1, the total dosage amounting to 1,140,000 units. At 11 p.m. on Aug. 3—i.e., nine days after beginning treatment—large urticarial weals suddenly appeared. The arms and legs were covered with them, and the patient complained of pain in the small joints. The temperature and pulse rate were not raised. There was a distressing skin irritation. Adrenaline hypodermically was given at once. His condition gradually improved after a few days, and he was discharged on the 8th.

The patient was readmitted the next day for a repeat of the penicillin course. This was started at once and three days later a mild urticarial reaction appeared. The penicillin was stopped after 1,620,000 units had been given.

Anaphylactic-shock-like Syndrome

Theoretically this may arise in certain subjects, previously sensitized to penicillin, who receive after an interval multiple parenteral injections, or even a single injection, of the drug. I have personally not seen such an occurrence. The case reported by Strazza (1946) presented what appeared to be anaphylactic shock, but skin lesions were also very prominent. O'Donovan and Klorfajn (1946) produced an anaphylactic-shock-like reaction in a previously penicillin-sensitized patient by giving him a single intramuscular injection of 15,000 units of sodium penicillin. Fifteen to twenty minutes after the

injection the pulse became quick and thready, and a throbbing sensation in the face, breathlessness, restlessness, pallor, cold sweats, and mild rigor occurred. Six hours later an oozing dermatitis of the face appeared. He slowly recovered in two days; a patch test became strongly positive on the third day.

Discussion

The frequency of these reactions to parenteral penicillin has been put at varying figures between 0.56% and 5.7%. The former is probably nearer the truth.

The aetiology is still a debatable subject. Some observers believe the reaction to be due to impurities. Others—and these form a majority—incriminate the active principle of penicillin. Commercial penicillins are doubtless increasingly more refined, but reactions are reported in ever larger numbers. The purest form yet known—the crystalline penicillin—gave in the hands of some workers positive skin tests in sensitized subjects. So long as penicillin remains unsynthesized a categorical answer is impossible. The search for specific serum antibodies has so far given no convincing results. All that is known is that a small number of people are susceptible to penicillin sensitization, and that this susceptibility is greatly enhanced in the presence of skin infections, especially those due to a fungus. Previous penicillin treatment, parenteral or local, can predispose to allergic reactions. We have seen that some of these may be very severe and call for cessation of treatment; attempts at desensitization have been made by some workers. O'Donovan and Klorfajn successfully desensitized one of their patients by repeated oral doses of penicillin.

Skin tests have given variable results; the patch test is easy to perform and is frequently positive. Dr. P. Headon suggested dry powdered penicillin on a square of gauze applied to the skin of the chest or arms. In Case 5 a positive result was obtained two hours after application, the patient complaining of itching in the right hand and swelling of the lips. The test was also positive in Case 4, in which it was performed at the time of recovery; the same patient had a negative intradermal test. Adrenaline hydrochloride hypodermically and ephedrine orally give rapid relief. These drugs should be repeated at frequent intervals in conjunction with small doses of phenobarbitone. "Benadryl," the new anti-histamine drug, may be found useful in the treatment of manifestations of penicillin hypersensitivity, especially in cases with marked urticaria.

What should be done if penicillin is again indicated in a case with a history of extensive urticaria following previous penicillin treatment, with subsequent recovery? Most observers are of the opinion that the drug should not be withheld if it is considered important to the treatment. The patient should be watched, and if an unusually severe reaction occurs cessation of penicillin will have to be considered. No useful purpose is served by changing to another commercial batch. Dr. A. E. Shaw suggested the use of skin tests to discover susceptible individuals, especially among those who have had (a) penicillin once or more previously; (b) a history of allergy, such as asthma, migraine, hay-fever; (c) fungus infection; (d) sensitization eczemas. Unfortunately skin tests are often negative in obviously allergic patients, and I wonder whether a preliminary injection of, say, 15,000 units would produce a clear-cut and mild enough reaction to indicate a penicillin reactor.

Summary

Thirty-eight cases of allergic reactions to penicillin have been collected from the literature and reviewed. Emphasis is laid on the manifestations due to parenteral administration.

Nine personal cases are added, of which 4 presented hydrarthrosis, 2 urticaria, and 3 serum-sickness-like reaction.

A clinical description of various types of reaction is given.

Susceptibility to reactions and the use of skin tests are dealt with. Frequency, aetiology, and treatment are also discussed.

NEUROMYELITIS IN MUMPS

BY

RONALD E. CHURCH, M.B., B.Chir.

Late R.M.O., Jersey General Hospital

the occurrence of nervous complications in mumps points to the fact that the mumps virus possesses potential or even primarily—according to Dopter (1910)—neurotropic propensities. The experimental work of Gordon (1927), in which eningitis was produced in monkeys by intracerebral injection of a filtrate of saliva from mumps patients, lends support to this view.

Systematic lumbar puncture in cases of mumps by French physicians has shown that a meningeal reaction in the form of a lymphocytosis is almost constant. Definite meningeal symptoms are much less frequent, Dopter reporting 9.8% of cases with meningeal symptoms out of a total of 1,705. Typical eningitis is even more rare, Roux recording three examples among 274 cases of mumps. Meningo-encephalitis may also occur, and Howard (1919) reports three cases in which the encephalitis occurred without parotitis during a mumps epidemic.

The above complications seem to occur at the height of the attack of mumps or shortly before or after it. The rarest complication, and one which appears to have a more delayed onset, is neuritis, or neuromyelitis. This may be localized or widespread. The third, sixth, seventh, tenth, and twelfth cranial nerves have all been reported affected, the commonest being the seventh—possibly through mechanical causes rather than virus infection in some cases. Paralysis of the serratus magnus has been reported by Harris and Bethell (1938). Lightwood (1946) recorded a case of a flaccid paresis of the right lower limb occurring eight days after the onset of parotitis. While in these cases are localized, a quadriplegia may develop, and five cases of this are reviewed by Collens and Rabinowitz (1928), their own case being of a man of 29 who developed a flaccid quadriplegia three weeks after the onset of epidemic parotitis, with complete bilateral facial paralysis, loss of the deep reflexes of the limbs and of superficial reflexes, and loss of position and vibration sense in the extremities. The cerebrospinal fluid was normal. Recovery was complete in four months. The four other cases were similar in the development of a quadriplegia: intervals varying from 7 to 21 days after the onset of parotitis. Position sense was lost in the case reported by Pitres and Marchand, and there was associated paralysis of both sixth nerves and left facial and right hypoglossal weakness in a case reported by Revilliod. Recovery was complete in all these cases, though Ford (1937) mentions fatalities due to paralysis of the diaphragm. The following provides another example of the quadriplegic type.

Case Report

A woman aged 37 developed bilateral parotid mumps on May 29, 1946, but ignored the attack so far as was possible, continuing with her housework. A week later she developed pains in the back between the shoulder-blades, which gradually became more severe until she was confined to bed. Two weeks after the onset of parotitis there was a gradually increasing weakness of arms, legs, and trunk until she was unable to sit or even move in bed. At the same time diplopia occurred, but there was no loss of sphincter control. The pain in the back continued all this time, but she had no headache. A week later, on June 19, the patient was admitted to Jersey General Hospital. On examination at this time she was pyrexial and mentally alert though very depressed. She was unable to move her position in bed; the tongue was dry and furred, and the parotid swellings had subsided. The fundi were normal; there was weakness of the third nerve bilaterally, paralysis of the left fifth nerve, complete paralysis of the right facial nerve, and weakness of the right accessory nerve. Cervical rigidity was marked. There was flaccid weakness of both arms with absent biceps jerks and weak triceps and supinator jerks. Position and vibration sense were impaired but other sensation was normal. Abdominal reflexes were absent. There was a paresis of both legs, greater in the left than in the right, with a positive Kernig sign, absent knee- and ankle-jerks, and absent plantar responses. As in the arms, position and vibration sense were impaired. Lumbar puncture was performed and a clear fluid, under 80 mm. pressure, was withdrawn. The Queckenstedt response was normal. The protein content was

20 mg. per 100 ml., there were 5 cells per c.mm., the W.R. and Kahn test were negative, and there was no change in the Lange test.

The patient was treated in the usual way for polyneuritis, including the injection of 50 mg. aneurine hydrochloride daily. The right facial nerve had fully recovered in seven days and the other affected cranial nerves in fourteen days. In five weeks she was able to walk, and in eight weeks returned home, with absent knee- and ankle-jerks as the only residual signs.

CONSERVATIVE TREATMENT OF ACUTE PERFORATED PEPTIC ULCER*

BY

A. HEDLEY VISICK, F.R.C.S.

Honorary Surgeon, York County Hospital; Consulting Surgeon, York City General Hospital

The history of the treatment of acute perforated peptic ulcer shows a gradual trend towards conservatism. Four distinct phases in treatment during the last twenty-five years can be recognized.

Stage 1.—Closure of perforation. Thorough peritoneal toilet. Flushing and mopping out of all exudate and foreign bodies. Multiple drainage-tubes.

Stage 2.—Closure of perforation. Limited cleansing and mopping of peritoneum. Removal of obvious foreign bodies. Single supra-pubic drainage for twenty-four hours.

Stage 3.—Closure of perforation. Aspiration of fluid only if obscuring site of ulcer. No drainage.

Stage 4.—Conservative non-operative treatment.

It is a very short but adventurous step from Stage 3 to Stage 4. For many years I had deliberately made no effort to remove the beer and carrots from the peritoneum because the task seemed hopeless, yet not one case of subphrenic abscess resulted. It was pneumonia and cardio-renal failure which were responsible for the fatalities that did occur.

Three further observations seemed to point the way towards greater conservatism. First, all surgeons must have felt on many occasions that surgical intervention had done more harm than good. It was no uncommon experience to find the perforation already sealed off. Operation then merely breaks down the adhesions and attempts to repeat what Nature has already effected. Secondly, during the course of the last 400 gastrectomies for chronic peptic ulcer we have several times noted the presence of sheets of adhesions which indicated that a spontaneous closure of an acute perforation must have occurred in the past. Finally, I can remember more than one obstinate patient who, although threatened with the serious consequences of refusing operation, has nevertheless survived and remained well.

In spite of these reminders that spontaneous recovery can occur it was not until Bedford-Turner (1945) reported a series of six cases treated conservatively that I had the courage to follow his lead. For twelve months I treated every case of acute perforated ulcer conservatively. There was no selection of favourable cases, but unfortunately the series is small. Taken in conjunction with many similar series all over the country, it did provide encouraging evidence in support of a trial for non-operative treatment.

Technique

The technique of treatment was as Bedford-Turner described:

Intravenous morphine, repeated as often as necessary to give complete relief from pain. Stomach wash-out with large-bore tube if a recent meal has been taken. Intermittent suction half-hourly through a Ryle tube passed via the nose. No drinks allowed for

* Part of a lecture delivered to the Leeds and West Riding Medico-Chirurgical Society, Feb. 15, 1946.

In York the incidence of acute perforation has fallen 44% during the last two and a half years, but the mortality of those who do perforate remains disappointingly high—22%.

A patient who has perforated more than once needs prophylactic gastrectomy. It must be very radical (at least 90%).

INOCULATION EXPERIMENTS AGAINST TYPHUS IN AFGHANISTAN

BY

ZÜHDI BERKE, M.D.

Professor of Bacteriology, Kabul, Afghanistan

Mild and severe typhus can be seen outside Kabul throughout the year. During the summer cases are only sporadic, but they become more frequent in the autumn; in winter the disease reaches its maximum incidence, with a further exacerbation when the snow begins to melt. There are no marked differences in clinical characteristics in different seasons of the year, but cases with severe haemorrhagic eruptions and, on the other hand, those without exanthemata diagnosable only by serological examinations, are observed. In the hospital of the central prison, Kabul, in one year out of 249 cases of typhus 213 persons recovered and 36 (14.4%) died.

When sera of doubtful typhoid or typhus cases are sent from the hospitals or the city to the Bacteriological Institute here, agglutination tests are done in six rows of tubes with six different types of microbes—i.e., *Salm. typhi*, *Salm. paratyphi* A and B, and *Proteus* OX 19, OX 2, OX K. One hundred and twenty-three sera positive for one, two, or three types of microbes gave Weil-Felix reactions (W.F.R.) for *Proteus* OX 19 (116 sera positive and 7 negative), for OX 2 (73 positive and 50 negative), and for OX K (33 positive and 90 negative). If the result of agglutination with OX 19 was negative, but positive with OX 2 or OX K or both, it was a sign that the sera were from cases occurring during the month of May or the autumn. Thus although the patients were suffering from typhus, their sera in 5.7% of cases gave a negative W.F.R. with OX 19 but positive results with one or both of the other types. The Weil-Felix test must be done here with all the three strains of *Proteus*, as doubt will be created in cases with negative serological results to one strain.

In May, 1937, severe typhus broke out in the region of Aybak, but the physicians there thought it was plague because pasteurillae had been found in patients' sputa. The disease was very severe, but exanthemata were seen in only a few persons, on the medial side of the thigh. My assistant was sent with all necessary equipment, and after making bacteriological and serological examinations, and experimental inoculations of material brought from the patients, he established that they were not plague cases. The W.F.R. was done with nine types of *Proteus* from the Lister Institute, London, results being positive with the OX 2 type but negative with all the others. This and further observations led me to the conclusion that different strains of *Proteus* were necessary for the diagnosis of the typhus of this region. The literature to date does not show OX 2 of *Proteus* as an independent agglutinin but as a coagglutinin, while in the Institute of Bacteriology at Kabul it has been found that free OX 2 agglutinin exists in the serum of typhus patients.

Blood Vaccine

In the winter of 1941 typhus was observed in and around Kabul. Prophylactic inoculation was possible only in Allied armies. In some institutions hygienic measures were taken to arrest the disease, and I inoculated with my vaccine those who had not yet been infected. The Government also permitted me to make experiments on the prisoners. The blood used in the preparation of the vaccine was taken in the second week from otherwise healthy patients who had rashes before the tenth day of the disease, and had high fever, positive Weil-Felix and negative Kahn reactions. It was put into sterile

bottles, defibrinated, and then filtered through sterile gauze into cylindrical bottles, after addition of 0.5% carbolic acid (10 ml. of 5% solution acid in isotonic saline to 100 ml. blood and kept one hour at 56° C. in a waterbath. I sometimes use 0.5 ml. of 5% formaldehyde in isotonic saline to 100 ml. blood instead of carbolic acid. After checking its sterility aerobically and anaerobically, this vaccine was kept in a refrigerator and warmed to blood-heat before use. It was inoculated three times subcutaneously into the abdominal wall 5 to 10 cm. from the navel, not more than once a week, the first dose being 2 ml., the second and third doses 4 ml. Four or five hours after the inoculation the patient began to feel unwell, the area of inoculation was hypersensitive to the touch and bluish in colour; but after about four days these signs disappeared.

In the prison at Kabul in 1942, 196 persons were inoculated in the spring and 368 in the autumn; other people who feared an infection or who found a louse on their bodies also came to the Institute of Bacteriology, Kabul, and were inoculated with my vaccine. Among the 196 prisoners not one case of infection was noted for six months. Between the sixth and seventh months 9 persons caught typhus; in 7 the disease had an uneventful course, but 2 died. Of the latter one was of the other was weak and suffered from consumption. Of the batch of 368, 13 caught the disease; 11 of these recovered and 2 died. As the vaccine could not be prepared for more than 80 persons at a time only those who so wished and who had not previously had typhus were inoculated. Although all the prisoners lived together, out of 13 cases only two feeble treatment patients died; but in the months of December and January when the disease was very serious among the untreated, 110 cases 89 recovered and 21 died. The result established the prophylactic efficacy of my vaccine, and these experiments showed that it could protect susceptible persons against the disease for 5 to 6 months. This experiment was made as a gesture of good will at a time when no better vaccine was available in the prison and in cases where there was no other way of giving active immunity.

American (Cox Type) Vaccine

In 1943 it occurred to me to try American vaccine, obtained through the Legation, and experimental inoculations were given as follows: May 7, 124 persons in the detention houses, 15 persons in the general prison; June 12, 100 persons in the women's prison; July 31, 150 policemen and 353 police soldiers in all, 922 persons. In the first week of September 691 soldiers of the First Division, and in the first week of October 85 soldiers of the Second Division—in all 1,542 persons—were inoculated (three inoculations, each of 1 ml. subcutaneously, at intervals of one week). Because the vaccine in the general prison was not sufficient, only those who consented, and among the soldiers only those recommended by the Surgeon Major were treated with the preparation of the Bacteriological Institute. All the other persons living together with the inoculated remained under control. Among the inoculated persons in the detention houses and the women's prison not one case of typhus was recorded during the first six months. In the central prison of the inoculated 2 fell ill but recovered; and of the uninoculated 15 caught the disease, 12 recovering and 3 dying. Among the inoculated policemen and armed police not one case was noted, but of the uninoculated 5 fell ill; 4 of these recovered and 1 died. In March, 1944, the American Legation again sent some vaccines, and 214 soldiers of the First Division, 23 of the Second Division, and 207 of the independent armed police troops—in all 658 persons—were inoculated. During one year after these inoculations not one case was noted among those protected, but among the unprotected in the First Division 23 caught the disease, 18 recovering and 5 dying; in the Second Division 11 fell ill, 10 recovering and 1 dying. Among the independent companies of the police soldiers 30 persons caught the disease; 27 of these recovered and 3 died. The result of these experiments—not one case occurring among the protected persons, but 9 deaths out of 64 unprotected—established the efficacy of the vaccine.

Summary

It has been established that in the typhus cases seen in and around Kabul, carrying a mortality of 14.4%, the sera taken from the

patients contain three types of agglutinin to *Proteus* in different proportions. One of them is the main type and the others exist as coagglutinins. In this region it has been found necessary to make the Weil-Felix test with all the three types of *Proteus*.

The vaccine prepared here has been efficacious.

In 1943, 3,122 persons—police soldiers, policemen, and prisoners—were inoculated with American typhus vaccine (Cox type), but, because sufficient vaccine was not available, controls were not inoculated, but remained in the same area. Although during that year the outbreak was not serious, cases and deaths were recorded among the uninoculated; among the inoculated, however, only mild cases were recorded, with no deaths.

Medical Memoranda

Two Unusual Clinical Manifestations of the Primary Phase of Syphilis

It has often been pointed out that many, if not the majority, of chancres do not conform to the textbook type. The following rather unusual cases which have recently occurred in one of H.M. ships show several points of interest.

CASE 1

This patient first attended on May 8, 1946, complaining of some soreness of the penis. He admitted having had intercourse eight days previously. On examination he was found to be suffering from a mild balanitis associated with a phimosis. The inflamed area was dressed with gauze soaked in eusol twice daily. All inflammation had subsided within 48 hours. A blood Wassermann was reported on as negative. Subsequently he was admitted to hospital, where circumcision was performed on May 15.

The patient next attended on June 21 complaining of a lump in the groin. He denied any further intercourse. The circumcision scar was found to be slightly oedematous and there was a moderate bilateral inguinal adenitis. The blood Wassermann reaction was reported as doubtful. On June 25 the surface of the scar was eroded and there was a distinct surrounding induration. Repeated dark-ground examinations were negative. On June 30 he complained of severe pain in the penis. The original scar had now developed into a deep craggy fissure encircling the glans, there was gross oedema and reddening of the whole penis, and the adenitis had increased. Dark-ground illumination revealed *Treponema pallidum* in large numbers, and the Wassermann reaction was now strongly positive.

CASE 2

This patient first attended on June 6, 1946, complaining of a lump in his right axilla and some upper abdominal aching. He denied having had intercourse during the preceding thirteen months. On examination a scab 1 mm. in diameter was found over the third right metacarpo-phalangeal joint; it was painless and showed no signs of any inflammatory changes. The right epitrochlear gland was enlarged to the size of a thrush's egg, painless, and of the consistency of rubber. The right axillary glands were also much enlarged, discrete, and painless. There was some tenderness over the splenic area.

The patient was observed at daily intervals. On June 12 the Paul-Bunnell and Wassermann reactions were reported on as negative. On June 14 there was some reddening and pain, associated with slight surrounding oedema, over the scab on his knuckle. Pus-forming organisms were present, and within one week ulceration had taken place. There was now a round lesion 1.5 cm in diameter with an ulcerated centre and indurated edge. Unfortunately syphilis was not reconsidered at this time, and dark-ground examinations were not carried out. The ulcer healed within three weeks and a thin papery scar remained. The adenitis persisted, however, and on further direct questioning the patient recalled that the original abrasion of his knuckle was caused through striking another rating on the teeth about ten days before first attending. The latter had been under my care for gonorrhoea and his blood Wassermann reaction had been negative, nor had he shown any clinical signs of syphilis. The Kahn reaction of both these patients was strongly positive.

COMMENT

Case 1 is of interest in that the site of inoculation was almost certainly removed at circumcision, yet the primary phase still developed in the circumcision scar. Case 2 is unusual in that the adenitis developed eight days before the chancre, thus throwing me off the scent. Burke states that about 50% of chancres are correctly diagnosed in the absence of any apparent associated adenitis; if the satellite bubo does appear it usually becomes evident about ten days after the chancre. Further, the case is a lesson that any sore on the hand of slow evolution should be repeatedly examined under dark-ground illumination.

I wish to express my thanks to the Medical Director-General of the Navy for permission to publish this paper.

P. D. GORDON PUGH, M.B., B.Chir.,

Reviews

A SWISS TEXTBOOK OF GYNAECOLOGY

Lehrbuch der Gynäkologie. By Prof. Dr. Hans Guggisberg. (Pp. 717; 354 illustrations. 72 Swiss francs.) Basel: Verlag von S. Karger. 1946.

This textbook is an excellent publication and reflects great credit on Switzerland. The publishers have been able to use exceptionally good paper and the print is of high quality. The coloured photographs are remarkable and most of the illustrations are well reproduced. The photomicrographs are perhaps not up to modern standards; many are over-exposed and some show failure to centre the illumination.

As in most Continental textbooks of gynaecology, much attention is paid to hygiene, constitution, and physiology, but less emphasis is placed upon the purely clinical side than is customary in this country; sixty pages are devoted to the chapter on affections of the urinary system, while only some nine pages are given to endometriosis. "Chocolate cysts" receive scant attention and there is little discussion of the conflicting theories. The treatment of prolapse is not dealt with in sufficient detail, and in this country we should regard the contribution as unsatisfactory in spite of the magnificent illustrations. The sections on carcinoma of the cervix and carcinoma of the body of the uterus are particularly good. Cervicitis is not described in adequate detail and too much emphasis is placed upon the chemical treatment of chronic cases. There is the usual difficulty in finding satisfactory illustrations of cervical erosions.

Apart from these minor criticisms the work contained in the book must be praised. The chapter by Prof. Neuweiler on gynaecological diagnosis is of exceptional merit and well worth careful study. Guggisberg's own contributions are well written and clearly expressed. It is a great pleasure to see again such an excellent specimen of a Continental textbook. The standard of comparison should be the British textbooks published before the war, and it must be admitted that such high quality was rarely, if ever, obtained in this country. In 696 pages there are over 350 illustrations, and the number of coloured plates is more than the average British publisher would allow. This new Swiss textbook should be able to compete with those of Stoeckel and Schröder.

PRODUCTION AND CONTROL OF MILK

Milk Production and Control. By Wm. Clunie Harvey, M.D., D.P.H., and Harry Hill, F.R.San.I. Second edition. (Pp. 512; 211 illustrations 3fs. 6d.) London: H. K. Lewis and Co. 1946.

Those who are familiar with the first edition of this book are aware of the wide field it attempts to cover. Even though it is restricted to liquid milk and avoids all consideration of milk products, it has nevertheless a long tale to tell. Broadly, it deals with the production of the milk on the farm, its transport to the dairy, its processing, and its final distribution. Special chapters are devoted to the nutritional value of milk, milk designations, milk legislation, and laboratory methods of control. In the new edition are included many of the changes that have occurred in the handling of milk during the last nine years. Not all the information has been brought up to date, but the authors may well plead that complete revision of any serious work in wartime was a major operation.

Though the book, in general, is on a high level, there are parts of it which in a future edition should be either omitted or edited by someone with specialized knowledge. This applies particularly to the chapter on laboratory control and to many of the bacteriological statements. Is it wise, for instance, to describe the method of isolation of pathogenic organisms from milk in a way that would have been adequate in 1910 but which now bears little relation to procedure in a modern laboratory? Why is there no mention of actinobacillosis, which is a much commoner disease in cows than actinomycosis? Why is it stated that the methylene blue is an all-or-nothing test, when the readings are taken every half-hour up to $\frac{4}{5}$ or $\frac{5}{5}$ hours? The same misleading comment could be made on the plate count. Several other criticisms might be put forward, but it

would be unfair to stress the shortcomings of this book. Taken as a whole, it is reliable and accurate and provides a very useful conspectus of the liquid milk problem, which no other recent book has attempted to give.

SILICOSIS

La Silicosis Pulmonar. By Dr. Hugo Dooner. (Pp. 195; illustrated. No price given.) Santiago de Chile: Empresa Editora Zig-Zag, S.A.

The author was at one time medical officer to a copper mine in Chile and later worked in a department of industrial hygiene in Santiago. In his book he first reviews the literature on silicosis and then discusses various forms of apparatus used for counting dust particles, paying particular attention to the impinger of Greenburg and Smith. He considers that certain individuals have a predisposition to the disease, especially those of a lymphatic type, with a tendency to fibrosis and keloid formation. He likewise mentions the view of von Bernath that certain persons become sensitized to silica.

A good deal of space is devoted to a review of the existing literature. In the mine at Potrerillos he used his own classification of three groups. In the first there was little or no physical incapacity and little or no fibrosis; people exhibiting these changes were examined annually. In the second group there was greater disability and more fibrosis; a change of work with monthly examination was indicated. In the third group there was marked fibrosis and gross incapacity, and those so afflicted were given life pensions. The cases classified in this way had no demonstrable tuberculosis.

The author has also made use of the classification of Pendergrass and Pancoast, modified slightly to suit local requirements. Cases with tuberculosis superadded appear at the end of this grouping. He finds that as a preventive measure the use of masks is of little value, since workers will not trouble to wear them. In conclusion he reviews the legal position in Chile with regard to compensation and quotes an extensive bibliography. This book is an elementary review of silicosis and contributes little new or original to our knowledge of the subject. It is written in Spanish.

INSIGHT AND ADJUSTMENT

Insight and Personality Adjustment. A Study of the Psychological Effects of War. By Therese Benedek, M.D. (Pp. 307. \$4.00.) New-York: The Ronald Press Company, 15, East 26th Street.

This is an important and topical book which should be a help and inspiration to everyone who has to deal with the readjustment of society after the war. Although written of Americans and for Americans its vision and humanity are applicable with equal force to our own social problems.

The first part deals along analytic lines with the psychological development of the individual and especially with the place of love in the integration of the personality. The stresses and conflicts involved in family relationships are dealt with and this leads up to the psychodynamics of separation. The second part deals with the soldier and his reactions to enlistment, army service, and demobilization, and his adjustments on his return to civil life. The third part is concerned with the family in war and traces the reactions of everyone to the four phases of service enumerated above; the relationships of the soldier with his mother, his father, his siblings, and his wife, both while he is away and after he comes back, are most sympathetically discussed. Parenthood during war as it affects both the mother and father, and the reaction of the soldier to his children, and especially to the child he may never have seen, are competently described. The fourth part discusses the sexual and social difficulties of the adolescent of either sex in time of war and shows how employment and the opportunity, indeed the necessity, to earn her livelihood has modified the outlook of the woman. The special problems of the woman who volunteered for service with the Forces is particularly well portrayed, and finally the outlook for the future in the age-long struggle between the sexes is discussed. A final note on the responsibility put upon humanity by the sudden ending of the war through the agency of the atomic bomb closes a thoughtful, wise, and well-informed book which ought to be procurable in this country.

ARTIFICIAL PNEUMOPERITONEUM

Pneumoperitoneum Treatment. By Andrew Ladislau Banyai, M.D. (Pp. 74 illustrations. 33s.) London: Henry Kimpton, 1946.

Artificial pneumoperitoneum, generally combined with paralysis, is at present enjoying a considerable vogue in the treatment of pulmonary tuberculosis, though as yet it is sharply divided about the indications for it and the results to be expected. Physicians interested in pulmonary tuberculosis will therefore be grateful to Dr. Banyai for bringing to them information from many sources about this procedure. His book contains a historical review and an account of the technique, of the physiological and morbid anatomical changes of the complications of artificial pneumoperitoneum. He discusses its therapeutic application not only in pulmonary tuberculosis but also in tuberculous peritonitis and enteric variety of abdominal disorders, including such diverse conditions as haemorrhage from the digestive tract and tuberculous salpingitis, and various broncho-pulmonary affections, including pulmonary abscess, asthma, bronchiectasis, and emphysema.

The material is derived from his own extensive experience and from copious references to the literature. The approach to the subject is rather over-enthusiastic and in places unbalanced. For the expert who will read with informed scepticism the faults will detract little from the value of the book as a source of information on this specialized subject; the general practitioner will be likely to obtain an over-favourable view of the results to be expected from the insufflation of air into the peritoneum.

Notes on Books

Dr. WILFRID SHELDON'S *Diseases of Infancy and Childhood* (J. and A. Churchill; 30s.) now appears in a fifth edition ten years after its first issue. Extensive revision has been taken, especially in view of the introduction of penicillin. Illustrations and a lot of new matter have been introduced and there has been a consequential slight increase in size.

The Care of Young Babies, by Dr. JOHN GIBBENS, has been revised for a second edition, after several reprints have been necessary since its first appearance. It is still an excellent book to the subject, essentially intended for mothers, but it might be studied by medical practitioners. The book is published by J. and A. Churchill at 5s.

Only four years have been sufficient to exhaust the second edition of the classical textbook *Practical Handbook of Pathology of the Skin*, by Dr. J. M. H. MACLEOD and Dr. I. MUENDE (H. K. Lewis and Co.; 50s.). This is largely owing to the fact that the American medical public proved to be as keenly interested as British workers in dermatology. Very little change has taken place in the preparation of the third edition, though the authors state that they have corrected a few errors and amplified descriptions. It remains the best, if not the only, handbook of dermatological pathology written in English, and we can only more warmly recommend it to the dermatologists for whom it is primarily intended.

For the ninth edition of *The Diabetic A B C* (H. K. Lewis and Co.; 4s.), Dr. R. D. LAWRENCE has included a post-war diet at the end of the book to replace the wartime Supplement. The Diabetic Association (9, Manchester Square, London, W.1) played a great part in arrangements to help diabetics during the war, and Dr. Lawrence in his preface urges every one of them to join it.

He Conquered Death, by MARGARET M. SHAW (Macmillan; 8s. 6d.), is a short biography of Sir Frederick Banting, narrated in the form of fireside talks; it will appeal to children aged 13 to 16. Some photographs of Banting are included, and reproductions of several of his oil paintings. In contrast to so much modern children's literature this book is pleasantly free from sentimentalism and the bitter belief that science is not subject to human values. Banting's retiring and virtuous life is described clearly and without sentimentality, both as an example to others and as a fine achievement in itself.

The quarterly *Journal of the History of Medicine and Allied Sciences* is printed in the U.S.A. for Henry Schuman, of New York, and published in this country by William Heinemann Medical Books Ltd.; price 12s. 6d. The longest articles in No. 3 of Vol. 1, July, 1946, are on the influence of the concept of monomania in French medico-legal psychiatry from 1825 to 1840, by Raymond Saussure, and a third instalment of Madge E. Pickard's study of the historical backgrounds of government and science in the U.S.A.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY DECEMBER 21 1946

NO

The Council of the British Medical Association met last week to be informed of the results of the plebiscite up to date, and to decide as a result of this information what report it should make to a Special Meeting of the Representative Body which will be held on Jan. 28. The R.B., being the policy-making body of the B.M.A., will then decide the course of action to be taken in the light of the Council's recommendation. The decision of the R.B., it is assumed, will be referred to the Negotiating Committee, as will the decisions of the other medical organizations forming this committee. Should the ultimate outcome be a united refusal to negotiate with the Minister on the Regulations of the National Health Service Act, then the Negotiating Committee will have no *raison d'être*, and it is possible that a new Committee under another designation will be formed. Some such step would seem to be essential so that the unity of the profession may be preserved as it has been all through the prolonged discussions and disputes since the days when Mr. Ernest Brown was Minister of Health. The paramount need of the profession at this moment is unity.

The Minister of Health has not taken into account the strong individualism which is characteristic of British medicine and responsible for its finest achievements. His enthusiasm for collectivism and centralized power has led him to misread the psychology of the practising doctor and to challenge certain fundamentals of his work. He is trying, in fact, to apply the principle of nationalization to the most individual of relationships between employer and employee—in this case the employer being the patient and the employee being the doctor. The medical profession has been warned by Mr. Bevan's phrase about the doctors not being ripe for plucking, by Mr. Greenwood's statement in the Second Reading debate that the Labour Party's policy of nationalization was unchanged, by the Lord Chancellor's revealing remarks in the Lords debate on the Third Reading which linked certification with basic salary. That the fears of the doctors are not groundless was shown in a startling fashion by the inept decision of the borough of Willesden to turn nurses and doctors out of hospital if they did not join trade unions against their will. The hasty retreat of the Willesden councillors and the repentant messages issued by Mr. Bevan and Mr. Isaacs have deceived no one. It is just that the moment is not yet ripe.

The medical profession has never been opposed to a comprehensive health service, and in the last Government it was reaching agreement with Mr. Willink on the principles of such a service because it was dealing with a Minister prepared to discuss points of difference and to negotiate so that the best interests of the public could be

served through a health service manned by doctors willing to co-operate in a great task. Mr. Bevan broke the concord between the medical profession and the department of which he became the new head. He refused to negotiate.

It was within this framework of ideas that the Representative Body this year decided, on seeing the final Act, to take a plebiscite of the whole profession, members and non-members of the B.M.A., on whether the organized medical profession should enter into discussions with the Minister on the Regulations under the Act; that the voters have answered as they have done; that the Council of the B.M.A. met last Wednesday to examine the results of the votes and to forward to the Special Meeting of the Representative Body on Jan. 28 this resolution:

"That the Negotiating Committee be advised that in view of the results of the plebiscite the Minister be informed that, because of the divergence between the principles of the profession and the provisions of the National Health Service Act, the Committee is unable to enter into discussions with the Minister on the Regulations to be made under that Act."

We may summarize the up-to-date figures of the plebiscite thus. They are given in tabular form elsewhere in this issue. Of all civilian doctors to whom voting papers were sent, 37% voted Yes, 44% voted No, and 19% did not reply. Of the first 4 Groups to whom voting papers were sent—that is, consultants and specialists, general practitioner principals, general practitioner assistants, and whole-time voluntary hospital workers—37% voted Yes, 55% voted No, and 8% did not reply. If we take Groups 2 and 3—namely, all general practitioners, both principals and assistants—32% voted Yes, 56% voted No, and 12% did not reply. It is quite clear that the first 4 Groups contain those who are directly affected by the Health Service Act. They are doctors now practising freely as individuals not employed by any local or central Government authority. If for the first 4 Groups the non-voters are added to the Yes voters (giving 45%) there is still an absolute majority voting No. If among general practitioners the non-voters are added to the Yes voters (giving 44%) there is an absolute majority voting No. Of all civilian doctors, if the non-voters are added to the Yes voters then there is not an absolute majority for No. Finally, of the total of those who voted, 64% in Groups 2 and 3—namely, general practitioners—voted No and 36% Yes; of Groups 1-4—general practitioners, consultants and specialists, voluntary hospital workers—59% voted No and 41% Yes; of all civilian doctors who voted, 54% said No and 46% said Yes.

The significance of these figures was discussed at length and with full awareness of the gravity of the situation at the meeting of the Council last week. The Council was forced to conclude that it had no mandate to negotiate. Though the overall majority of those voting was small in favour of No, this No could not by any stretch of the imagination be interpreted as Yes. But when the Council came to examine the figures of those who would be most vitally affected by the new Health Service Act the proportion of those voting No was considered to be a sufficient majority to justify the Council's recommending the Representative Body not to negotiate with the Minister of Health on the Regulations under the Act.

The British Medical Association, the Negotiating Committee, and the Minister of Health are now for the first time fully informed of the considered opinion of the medical profession on the Act and its implications. In the recent past the Minister and various medical publicists have referred to a mythical large proportion of those favouring the Government's health scheme. These matters are now put beyond guessing through a plebiscite which has been answered by over 80% of the medical profession in this country—a truly remarkable poll. No one could or should underestimate the gravity of the situation the poll has revealed. No one, least of all doctors themselves, can be otherwise than gravely disturbed by this profound division between the Minister and those upon whom he must rely to operate the National Health Service Act. The general public and its representatives in Parliament cannot fail to be dismayed when they see on the eve of the putting into force of the National Health Service Act that its provisions are such as to conflict with the principles laid down by the Negotiating Committee, representative of all sections of medical life. Both people and Parliament must surely believe that there is something radically wrong in this Act if the majority of those who are asked to work in it declare by a vote that its provisions are such as to convince the majority of British doctors that the Act is against the public good. For this is what the vote means.

In framing his Act Mr. Aneurin Bevan refused to negotiate with the medical profession. This was a one-man decision. The medical profession now contemplates refusing to negotiate with the Minister. This is a decision reached by more than 20,000 doctors—those saying No. The one decision is dictatorial: the second is democratic in the real meaning of the word. It but remains to be pointed out that if the Minister proceeds with his Regulations and fixes an appointed day those doctors who wish to work in it will do so and those who wish to remain outside it will do so. We believe that unless some radical change is made between now and the appointed day the numbers of those deciding upon the latter course will increase. It is for the Minister to find a way out of this impasse.

DEFECTIVE COLOUR VISION IN INDUSTRY

Defective colour vision, more commonly and less accurately called colour-blindness, affects probably 8% of the male population. The incidence in women is very much lower. Though defects in colour vision may result from pathological lesions in the eye, they are generally an inherited abnormality transmitted to their sons by the daughters of affected men, these women being themselves unaffected. Colour defects occasionally arise in girls who are the daughters of affected men and of women who though unaffected are carriers. Any condition with such a high incidence in the male population cannot be a matter of indifference, and defective colour vision may be a considerable handicap in particular jobs. A valuable study of this aspect is the *Report on Defective Colour Vision in Industry* compiled by a committee of the Colour Group of the Physical Society. This report was presented by the chairman of the committee, Dr. J. H. Shaxby, to a meeting

of the Group on Thursday, Dec. 19. Though much of the comprehensive document is not new to the medical reader it is none the less welcome for its explicit account of the types of colour defect met with clinically, and for its appraisal of the many different methods used in detecting such defects. In a subject smothered with theoretical speculations it is particularly gratifying to find a straightforward factual statement. That colour defect is a matter of importance in the Services and on the railways is, of course, well known, and in these occupations tests of variable stringency have been applied for many years to ensure that colour defectives are not employed to the danger of themselves and of others on tasks requiring the recognition of colour signals. It is not generally appreciated, however, how great a part is played by colour in industry.

Problems of colour are less likely to arise in the manufacture of cottons than of woollens, mainly because the difficulties are deferred to the dyeing, printing, or merchandizing stages in the case of cottons, whereas with woollen goods a high standard of colour vision and colour discrimination is necessary in a large proportion of the workers in the dyeing office where colour matching is done. Moreover a large number of operatives require to be able to distinguish between different yarns, which may show only very slight colour differences. One firm of cotton and woollen dyers considered that at least 50% of their employees needed good colour vision to do their work efficiently, though other firms put the proportion at no more than 10 to 20%. The matching of stockings in pairs is apparently a fairly complicated process and employees must pay attention to five points, one of them being slight differences in shade. The observation of the head of one firm that there was a close relation between poor work and tired feet is interesting. Rapid discrimination of fine shades and differences requires physical efficiency no less than mental alertness and an adequate colour sense. One shop assistant explained that he used to astonish customers who asked for ties or socks of a particular colour, but he had since learned to shuffle out a mixed batch without comment, thus successfully camouflaging his colour defect.

Good colour vision is necessary in many departments of the electrical industries because coloured wires and coloured diagrams are often used. Sometimes the degree of discrimination involved is such that even those whose colour vision is normal may find it difficult. A colour defective tested at a particular works was as often wrong as right in matching a series of samples. This man worked by trial and error and used subsidiary clues such as the thickness of the wires. In illuminating engineering the growing practice of using discharge lamps, of which the light is concentrated either in a few lines of the spectrum or in relatively narrow bands, has given trouble to employees lacking normal colour vision. Slight contamination of lamp parts may result in a temporary change in the colour of part of the electric discharge, and this may readily escape the colour-defective engineer.

In printing and photo-engraving the proportion of operatives concerned with colour varies from 30 to 70% in different firms. Fine colour discrimination is particularly important in the manufacture of printing ink, and one firm

found that two of their colour matchers who had passed the age of 65 were no longer reliable. Colour discrimination does, of course, tend to become less accurate with increasing age.

Colour is important in mining because of the signals used. This applies still more to the oil industry, where dangerous temperatures, critical levels, and the like are often indicated by coloured signals. Good colour vision is probably not essential for most chemists, but it is of importance in industrial chemists working on paint or dyeing. In analytical chemistry colour defects are of less significance since the development of various automatic electrical methods which have replaced titrations involving fine end-points. Histology, bacteriology, and pathology are singled out as medical activities in which the colour defective is at a disadvantage.

In most industries methods of testing for colour defects are somewhat primitive or totally lacking. The general view seems to be that men will find their own level, and those men who have difficulty in a particular branch of the industry will automatically gravitate to another department in which their defective colour vision does not matter. Even where fine colour discrimination is essential, tests are the exception rather than the rule. The comment made by the director of one firm, "We depend very largely upon Bill," exemplifies the general attitude. It seems to be usual to rely upon the sound judgment of a particular workman for critical processes. That this is not altogether satisfactory is obvious, and the report rightly stresses that much could be gained in efficiency, in the personal happiness of employees, by adequate prevocational tests. One obvious place for such testing is the school, and from a preliminary investigation it would appear that group-testing could be undertaken by using an epidiascope to project test cards. The School Medical Services are already hard pressed, but this suggestion, no less than the alternative suggestion for testing entrants into particular industries, deserves consideration. The frequency of colour defect would justify the labour involved, and the mass of useful information incidentally obtained would be of advantage in the study of colour vision. There might also be brought to light information which would allow us to check the observation that "even some Royal Academicians are stated to have been colour-blind." It would be interesting to know whether this was an ophthalmological or an aesthetic judgment.

THE CHRISTMAS PUDDING

We have been deprived of many good things for the last seven years, and one of the most to be lamented is the Christmas pudding—now unknown to young children (lower age groups is perhaps more appropriate to these austere times) except as a name attached to an otherwise barely recognizable article sponsored by the Ministry of Food or as one of those cream-capped Himalayan mounds still depicted on Christmas cards. The time may not be far off when only scholars and their like, who retain childhood's power of confusing the symbol with reality and bringing it to life, will understand what was meant by a "groaning board."

Libraries will be combed for dusty cookery books; an egg-stained page will evoke the same thrill as do De Quincey's manuscripts stained here and there with circles of laudanum where he put down his tumbler. A particularly fine recipe will be hailed as evidence of an art now lost, like that of colouring mediæval cathedral glass. The following recipe indicates how rewarding such a pursuit might be:

Constituent	Quantity	Approximate Calorie Equivalent
Suet	6 lb. (2.8 kg.)	20,000
Flour	4 lb. (1.8 kg.)	6,648
Demerara sugar	2 lb. (0.9 kg.)	3,646
Raisins	6 lb. (2.8 kg.)	7,314
Currants	6 lb. (2.8 kg.)	7,236
Sultanas	2 lb. (0.9 kg.)	2,470
Candied peel	1½ lb. (0.7 kg.)	1,873
Chopped almonds	½ lb. (0.1 kg.)	680
Eggs	48	3,984
Grated peel of 3 lemons		
Brandy	1 bottle	3,500
Port	1 bottle	1,400
	Total	58,756

To compound fifty-five thousand calories (allowing for wastage in cooking) in a single pudding seems almost inconceivable in an age when we more readily concentrate them in a bomb. The present daily calorie intake per head is, on the average, about 2,750, or one-twentieth of the pudding—a portion that might well be eaten in a single large helping. But who cares about the calorie-content of such a creation? Its sustenance is of the spirit, not of the body. The mind is enriched and tranquil after such a meal, free to dream peacefully of those sunlit lands far over the blue, untaxable sea where grapes turn to wizened raisins in a day and the orange ripens. And what more appropriate to the season's international concord than the pudding's constituents?—brandy from France, the West Indies' sugar, almonds from Italy, lemons from the Levant, and Portugal's wine. From hurrying to gain "the poor benefit of a bewildering minute" life slows after such a dinner to a human pace. For just as our hearts quicken at the expense of diastole, our hastened lives have lost much relaxation and leisure. It is the function of Christmas puddings to restore this indispensable refreshment.

If we stress the cultural qualities of the Christmas pudding rather than the nutritional it is because they are more likely to be overlooked. The metabolic implications of such a mountain of food are too obvious and those of the palate too tantalizing to dwell, to dilate upon further. We turn, rather, to the question of whether scarcity of food will cause us to revert to a more primitive state. Preoccupation with food, the mark of primitive societies, is certainly characteristic of our own to-day. It was once a common practice all over the world for the tribe to kill its king if the food supply failed; we threaten Governments nowadays. In time of dearth the Mexican Indians propitiated the gods with human sacrifices; we dispatch Ministers. The ritualistic dances and prayers of former times have given way to queueing and form-filling, petitions through trade union channels, and certificates from doctors; and the passion that introduces the topic of food into every conversation once filled the caves of Southern France with paintings of bison and deer. The old charms and formulae have come back to us in a new guise.

Dr. Johnson would to-day find ample evidence for his declaration that "human life is everywhere a state in

which much is to be endured and little to be enjoyed." Our reduced Christmas pudding is as much a sign of the times as is our swollen Civil Service. Circumstance forces restrictions upon us; perhaps we shall in time become conditioned, like the rats, to finding our way quickly through the maze. More fearful, however, than the shrivelling of our pudding is the speculation whether it may at some time be forbidden altogether—a calamity that did occur once. In 1644 a Puritan Government prohibited the observance of Christmas by Act of Parliament. This must be a tempting precedent to our modern Puritans, and we shall watch developments closely. Meanwhile the season is here; the shops have been emptied and the stockings filled; and doctors will soon be dealing with the wish-bones, beads, sixpences, and tin soldiers that children cram down their throats whether there is a pudding to follow or not. A merry Christmas!

CONSERVATIVE TREATMENT OF PERFORATED ULCER

For more than half a century the management of perforated peptic ulcer has epitomized all that is dramatic in modern surgery. The *mise-en-scène* is familiar to all: the patient lying in his agony in the receiving-room, his face pale and drawn, and his very speech hampered by the certainty of increasing his suffering; the surgeon calm and confident (for here is usually a diagnosis beyond doubt); and, in the background, the imminent presence of death. The action moves to the theatre and then to the ward, where in a few days the patient, happy and comfortable and out of immediate danger, extols the skill of his surgeon. It is the surgeon's apotheosis. The fact that some of the very few patients who refuse operation recover and that some of the operated cases die has not seemed to detract from the general truth of this picture. Is this fantasy? When we try to ascertain the exact facts of the situation they appear to throw such doubts on its validity that some surgeons have recently abandoned the operative treatment of perforated ulcer in favour of conservatism. The evidence for such a revolutionary step will be weighed by all thoughtful surgeons, and their verdict will soon be forthcoming.

Most experienced surgeons would give their operative mortality for all cases of perforated ulcer at between 5% and 10%—a figure supported by Morley's recent report¹ of a mortality rate of 8% and by Houston's² figures for 1943 and 1944—8.2% and 6.3% respectively. A mortality of below 10% is satisfactory in the present conditions, but we must face the fact that the general mortality for the whole country is possibly in excess of 20%. Thus Hedley Visick, in the current issue of the *Journal*, gives the operative mortality at York as 22%, and Houston's figures for 1939–42 are not far below this. It must also be remembered that surgeons rarely publicize high mortality rates. What has been said of the surgery applies *a fortiori* to the anaesthetic, and the experienced anaesthetist approaches these cases with respect. The post-operative chest morbidity rate of perforated ulcer was given by King³ as 66%—by far the highest rate for all abdominal operations in his series—and many of the deaths are the result of these complications. There can be little doubt that a greater use of derivatives of curare for these cases and a wider distribution of specialist anaesthetists will improve the mortality and morbidity rates considerably.

Recently Bedford-Turner,⁴ Hermon Taylor,⁵ and Hedley Visick have advocated a conservative regime in these cases. Hermon Taylor has treated the greatest number—twenty-eight—with four deaths, and a mortality rate of 14%. He considers that one of these deaths could have been avoided by early operation and that six of the patients who recovered under conservative treatment would "have stood little chance with operation." From the notes it appears that the rest were cases of early perforation and would probably have recovered after operative treatment. The import of these figures is that under surgical management 9 of the 28 patients might be expected to die instead of the four who actually died under Taylor's regime. A mortality of 14% is certainly better than one of 32%, but on Taylor's admission the figures rest largely on the "clinical judgment and report of his house-surgeons; and, in any event, a mortality rate of 14% does not offer reasonable grounds for abandoning a routine which has repeatedly given recovery rates over 90%. Similar criticisms can be applied to Hedley Visick's figures, and it is interesting that the three patients who died were all under 60, and that the perforations had occurred less than twelve hours before death.

It is instructive to compare the theory of the conservative school with more orthodox opinion. Visick states that it is unnecessary to remove the peritoneal fluid and extravasated particulate matter: from this statement there will be little dissent. A great part of the fluid content of the peritoneal cavity is an exudate from the endothelial surface which dilutes the irritating misplaced gastric contents. Gross particulate matter is rarely found, and indeed, as perforation rarely exceeds a few millimetres in diameter it is not to be expected. Few surgeons do more than aspirate the contents of Rutherford Morison's pouch as a reserve drainage for the very late cases. Those who operate seek to close the perforation, believing that the peritoneum can take care of itself if further soiling is prevented. The fact that perforated ulcers can close spontaneously has been known to observant surgeons for many years, but to argue from this that any given case is likely to do so is surely a logical error and may have dangerous implications.

At the present time the results of operative treatment in the best hands are so much better than those advanced by the advocates of conservatism that most surgeons would endorse Prof. Morley's opinion that non-operative treatment should be reserved for the poor-risk cases only. An improvement in the national mortality from this disease is more likely to result from earlier diagnosis and admission to hospital. One implication of great importance which emerges from this work is the use of gastric aspiration in cases of perforated ulcer if, for any reason, operation is to be deferred. If this alone is absorbed into routine surgical practice the protagonists of conservatism will have rendered a useful service.

BACTERIAL CHEMISTRY

Medical practitioners, having been introduced during their laboratory training to the hitherto unexplained distinction between Gram-positive and Gram-negative bacteria, cannot but be impressed by the discovery, due to Dr. H. Henrici-Olsen, the Birmingham City bacteriologist, and Prof. M. Staey, the University of Birmingham, that this empirical division has a chemical basis. The staining quality, characteristic of the Gram-positive bacterium, was found in 1943 to be associated with the presence of magnesium ribonucleate within the organism, whereas Gram-negative bacteria w

⁴ *British Medical Journal*, 1945, 1, 457.

⁵ *Lancet*, 1946, 2, 441.

characterized by the absence of this substance. That there could be some such distinction was scarcely surprising in view of the well-known significance of this test in relation to, for example, penicillin sensitivity. It was, indeed, largely on this account that Dr. Henry and Prof. Stacey undertook their recent investigation, as is made clear in their communication on the subject to the Royal Society.¹ Their main investigation was carried out on *Cl. welchii* and mast cells; but confirmatory evidence was also obtained from certain anaerobic bacteria; aerobic spores, including *anthracis*; and certain strains of streptococci. In each case the first step was to obtain an extract from the organism by suspension in 2% bile salt in normal saline. After extraction in this way the cytoskeletons of the organisms were found to have suffered a reduction in weight, and, except for a few obstinate individuals, to show a Gram-negative instead of the usual positive reaction. Further, it was found that the extracts which had been obtained after fractional separation could be reabsorbed by the cells from which they had been taken, after the latter had been treated with a reducing agent. Cytoskeletons so treated gave the original positive reaction to the Gram test, though looking, as Prof. Stacy expressed in his Tilden Lecture before the Chemical Society, "as if they had knocked about a bit." Further fractional separation of the bile salt extracts led to the isolation of magnesium ribonucleate, which was identified both by a characteristic absorption band at 2,600 Å., and by its degradation products. In addition, it was shown that magnesium ribonucleate prepared from commercial sources was equally effective in restoring the Gram-positive reaction to cells which had been thus treated. Finally, normally Gram-positive organisms were subcultured in a medium deficient in magnesium, and without further treatment were found to give a negative reaction.

It would seem therefore that a convincing, as well as an elegant, demonstration has been provided; and that Christian Gram, whose test was first mentioned in 1883, must be credited with a criterion of greater biological significance than could have been realized at the time. Prof. Stacey's laboratory has been responsible, in addition, for much detailed work on the complex polysaccharides associated with bacteria—long-chain and branched-chain structures based on a variety of ring formations, one of which has not previously been associated with any form of life. No less remarkable, in another direction, has been the achievement of Avery in New York, quoted by Stacy in his Tilden Lecture, in transforming Type 2 pneumonia anti-serum into Type 3 by laboratory methods. With the protein, polysaccharide, lipid, and nucleic acid components of bacteria available for investigation, either separately or sometimes as it appears in combination, the scope for bacterial chemistry is anything but limited; and from the beginnings already made an ample harvest may well be expected.

RADIO-COBALT

Much new information about the artificial radioactive isotopes which have been produced as by-products from atomic energy research has lately been released. In addition it has been stated, on the authority of Dr. J. D. Cockroft, Director of the Ministry of Supply's experimental station, that the first of the "piles" to be built in this country will be operating within "the next few months." It may be assumed that the "pile" will be a small one, intended in the first instance for the production of such of these new isotopes as may be required for research and in clinical use. The research use will probably in the long

run be the more important, for the possibilities both in physiological and chemical research which will result from the availability of radioactive "tracer" atoms of a large number of chemical elements, including carbon, will be very far-reaching indeed and can scarcely be exhausted inside a generation. In the case of some elements the most convenient isotopes for research are those produced in a "pile"; in the case of others those produced by "cyclotrons," of which the most powerful in this country—that at the University of Birmingham—should be ready for operation within a similar period.

For clinical medicine, however, the most immediate consequence will be the production of radio-cobalt as a substitute and supplement for radium. This, Dr. Cockroft indicated, will be among the early functions which the Harwell Station will be in a position to undertake. The radioactive isotope of cobalt is Co^{60} . It is prepared by the neutron bombardment of normal cobalt, Co^{59} . This is done by placing a specimen of normal cobalt in a "pile," and leaving it there for some months. The half-life of Co^{60} has been quoted as 5.3 years. The beta-radiation produced is "soft"; the gamma-radiation has been stated to be of two frequencies corresponding with x rays of 1.1 and 1.3 million volts. For radium the top figure corresponds to about 2 and the filtered average 0.8 million volts. Though experience will be necessary to assess the clinical significance of this relatively small difference, there can be little doubt that the claim of the physicists to have produced an effective substitute for radium must be substantially accepted. Moreover, the way will be opened to a considerable increase in the scale of use should this be found desirable. A comparatively small "pile" in Canada is stated to have produced, in six months' operation, the equivalent of 100 curies of radium as an incidental item in the course of research. It was presumably on account of this outlook for increased availability that powers have been taken to concentrate the distribution of all radioactive substances through a single channel.

Of even greater interest scientifically, if not to clinical medicine, is the fact that U^{233} , the new isotope of uranium which is formed from thorium, is the parent of a hitherto unknown radioactive series, which includes a new isotope of radium— Ra^{225} . The three existing radioactive series are those which take their names respectively from uranium, actinium, and thorium. The new series is comparable with the other three but differs from them in the fact that bismuth rather than lead is the end-product. Ra^{225} is not the only isotope of radium which has been artificially produced. All, however, have relatively short half-lives. Moreover, the quality of the radiation produced is a property of the particular isotope concerned, rather than of the chemical element. There is accordingly no more reason why the radiation produced by any of these radium isotopes should resemble in properties that from normal radium; and, in fact, as already indicated, it is Co^{60} rather than these new radium isotopes which most closely imitates the radiation from natural radium.

"CERTIFICATES REASONABLY REQUIRED"

A correspondent informs us that a few mornings ago a patient called at his surgery to ask for a medical certificate. On being asked what kind of medical certificate was required and for what purpose, he explained that he wished to buy a tricycle as a Christmas present for his small boy. The child wanted a tricycle, and the good father had at last managed to find a shop which had one in stock. He had approached the shop assistant and had been informed that he could have the tricycle only on production of a medical certificate.

Medical certificates, apart from those needed for matters medical, are officially required for priority supplies of milk, eggs, and soap; for special adjustments of food rations; surgical corsets; extra fuel for invalids; and extra petrol for invalids. Every general practitioner must have signed hundreds of certificates for articles of this kind and as many more for articles which are not officially in short supply. There seems to have been a tendency on the part of retailers to ask for medical certificates in the hope of diminishing to manageable proportions the number of people anxious to obtain such articles as vacuum flasks. Insurance practitioners have long been reconciled to the certificates required for the purposes of National Health Insurance. Form R.M.50 has become all too familiar, and wartime shortages which have continued into the uneasy peace have made necessary, at least to the patient, many other certificates, all of which make additional demands on the time and energy of the overworked practitioner. Olive oil, liquid paraffin, and glucose can rarely be obtained without a written recommendation from a doctor. Certificates are required for children who are absent from school and for children who wish to return to school. A healthy young woman who is likely to be pregnant for nine months must have a certificate to that effect every three months. There is still an astonishing variety of certificates designed to bring home from abroad husbands and sons who, in the opinion of their womenfolk, have been away too long. Those medical officers who served on Compassionate Boards in theatres overseas will recall the type of certificate which ran: "Mrs. X is suffering from alarm and despondency which is not likely to be relieved until her husband returns home."

Familiarity with the certificates required by Orders, by Regulations, and by various enactments seems to have inflamed a desire for more and more certificates which are not officially required but which are in the patient's view just as essential. There is a growing burden of certification which weighs most heavily on the general practitioner. The big majority of practitioners are conscientious, and the more conscientious they are the more time they must devote to certification, a great deal of which seems to be unnecessary. Some of them may already have noted with foreboding Clause 33, subsection 2(d), of the National Health Act. This lays down that under the arrangements for general medical services regulations shall include provision "for the issue to patients or their personal representatives by medical practitioners providing such services as aforesaid of certificates reasonably required by them under or for the purposes of any enactment." The interpretation of "reasonably required" may well be strict. But on the other hand it may continue to be interpreted so widely as to make a medical certificate a prerequisite for even the simplest Christmas shopping.

MR. HYND CHOOSES

The British zone in Germany has been short of food, and we commented on this in the *Journal* of Nov. 30. It is also short of intellectual food, and a few weeks ago Sir Ernest Graham-Little asked Mr. J. Hynd whether it was his responsibility to choose those British newspapers allowed to circulate in Germany. He also put the pertinent question to Mr. Hynd whether politics had any influence on the selection. Mr. Hynd replied, "No," and said that newspapers and periodicals could be sent through newsagents or dealers by post to individuals in the British zone or the British sector of Berlin. He added, too, that he was responsible "for selecting the British newspapers and periodicals supplied at public expense to certain German politicians, officials, and editors." Mr. Hynd then gave a list of newspapers and periodicals which he had selected for display

at information centres in the British zone and the British sector of Berlin. Among the 27 selected are only two which seem to have any bearing on science—namely, the *Geographical Magazine* and the *Lancet*. We find ourselves excluded in the good company of *Nature*.

HYPERTENSIVE RETINITIS IN ADRENAL TUMOUR

The study of retinal lesions in the hypertensive diseases has greatly helped the classifying of these affections. Though all the hypertensive retinopathies have retinal arteriosclerosis in common, the vascular changes vary considerably, and the retinal changes are sometimes pathognomonic. Thus the appearance in diabetic retinitis is distinct from that of renal retinitis, which, however, is barely distinguishable from the retinitis of malignant hypertension. Essential hypertension displays a milder picture, and the changes seen in such apparently transitory affections as toxæmia of pregnancy appear to be capable of spontaneous resolution. Apart from this solitary example of recovery—solitary, if the retinitis of trench nephritis is excluded—the prognosis in the retinopathies of vascular disease is not good either for visual function, as in diabetic retinitis, or for life, as in the retinitis of malignant hypertension and chronic nephritis. Essential hypertension occupies a place midway between these two. The changes are usually progressive and reflect a worsening of the general affection, though occasionally there is considerable recovery. Surgery has helped in a few cases in which an underlying factor could be removed—for example, intermittent obstruction of the ureter—or in such cases as those in which operations on the sympathetic nerves have been successful in checking the advance of the hypertension. None the less, the presence of retinal lesions in a hypertensive affection must be regarded as a serious complication and frequently of grave prognostic significance.

In a case report of retinopathy in a patient with adrenal medullary tumour (pheochromocytoma) Rodin¹ shows that the successful removal of the tumour led to the resolution of a marked retinal lesion. The retinopathy was in many respects similar to that seen in malignant hypertension, though not so severe. Within fourteen weeks after operation there was considerable improvement, and within twenty-six weeks the improvement was quite striking. Three and a half years after removal of the tumour the retina was normal.

The retinal lesions in adrenal medullary tumour are presumably the reflection of the permanent or paroxysmal hypertension seen in the course of the disease, and, as the hypertension itself is probably due to the liberation of large amounts of adrenaline or an adrenaline-like pressor substance by the tumour, it is not altogether unexpected that surgical treatment should check and even reverse both the hypertension and the retinopathy. Though this tumour is rare the possibility that it may be the exciting factor in cases of hypertension, particularly in young patients, is worth bearing in mind.

Prof. F. C. Bartlett, C.B.E., F.R.S., will deliver the Oliver-Sharpey Lectures on Tuesday, Jan. 21, and Thursday, Jan. 23, at 5 p.m., at the Royal College of Physicians. His subject is "The Measurement of Human Skill."

The date for receiving Plebiscite Forms has been extended to Jan. 6, in order to give those in the Services especially a chance to vote. The final count will be announced shortly after that date.

MEDICINE IN DACHAU*

BY

HENRI ROSENCHER, M.D.

Of 293,000 French people deported to Germany 42,000 came back, and 65% of these were found to be in bad health on their arrival in France. In this article, the medical aspects of life in a concentration camp are described, the facts being taken from Dachau, where I spent 8 months. The subject is considered under four headings—hygiene, morbidity factors, medical organization, and the pathology of the internee, the part played by starvation and overcrowding being emphasized, with a final note on the commonest sequelae of life in the camp as shown by a follow-up of 1,000 cases in the Department of the Seine.

Hygiene

At first glance Dachau would appear to be a model camp. The visitor (assuming that his entry were possible) would be impressed by the football ground, the clothing stores full of garments, the fine shower-baths with their modern heating installation, the spotless kitchens, and the charming lay-out of the buildings with flower-beds and an avenue of poplars. The *Revier* (sick-bay) would seem amazingly clean and tidy. It included rooms for eye and E.N.T. clinics, a physiotherapy room with the most modern apparatus (even an electrocardiograph), a big dressing-station, two magnificent operating theatres with a sterilization room, an x-ray department, a dental clinic, a well-fitted laboratory, a well-stocked dispensary, and beautiful parquet floors to the wards. If, further, the medical routine of the camp were described—the bath and disinfection on entry, the initial medical examination complete with radiography, the insistence on daily hygiene, the regular routine examinations and the formidable total of medical personnel in the camp—the visitor could not but marvel at the German genius for organization.

But the inmate saw a very different aspect. On arrival he was stripped of all he possessed, shaved all over, and conscientiously rubbed with a carbolic solution so strong that it frequently caused severe burns. The shower might be boiling or ice-cold, and was followed by many hours of waiting, naked, hungry, and cold, for an issue of camp clothing. The entire operation was repeated almost monthly, when all clothing was sent for an alleged disinfection in an apparatus the maximum temperature of which was admirably suited to the further development of the nit, and which often failed to kill the adult louse. This operation was in any case useless, since only sections of a room were done at a time, and it never included the infested mattresses. Its only result was to cause the death by exposure of the less hardy prisoners (100 deaths on one occasion, when a party remained naked for 36 hours in the month of February).

The daily toilet of the prisoners, although in theory obligatory, was hampered by total absence of soap, a time limit of 30 seconds per person per tap, and the fact that the wash-room was also a mortuary, necessitating much manoeuvring over and among corpses. The scrupulous cleansing of barrack-rooms each day did not prevent the bedding from swarming with fleas, lice, and bugs.

Factors Influencing Morbidity

As a killer, cold proved of great service to the S.S. Thus at Natzweiler, three-quarters of the Russians died after standing naked in the snow for 24 hours after a hot shower. The twice-daily roll-calls in the snow (the all-time record at Dachau was a roll-call lasting 60 hours), the snow-clearing parties, and the medical inspections to determine fitness for work, when the candidates waited naked out of doors for the S.S. doctor to look at their hands (sole criterion of fitness), all helped in the work of extermination. It is unnecessary to mention the inadequacy of clothing and bedding. To the cold was added *fatigue*. In the closed (non-working) blocks, 16 hours a day was often spent standing outside, while in the open (working) blocks the long hours of toil and roll-calls left only four hours a night for sleep.

The overcrowding of barracks left an average of 0.5 to 0.75 cubic metre of air per man, not to mention the presence of the corpses, which remained there perhaps for a week and were sometimes reinforced at the rate of 50 per night per block. And all this was added to a background of continuous *hunger*. Table I shows the food distributed in the closed blocks in a period of relative abundance—September, 1944. The calorie values may

seem low for individual products, but it must be remembered that, for example, the margarine had only 10% of fat, and the cheese was pure casein. The workers in the open blocks had a daily supplement of 260 to 290 calories. In March, 1945, there was a sharp drop in the rations, as shown in Table II.

Medical Organization

There were at first no doctors in concentration camps. One could either be alive and at work or dead and in the crematorium. When the *Revier* was first instituted medicine and surgery were practised by persons of doubtful antecedents among the inmates. In June, 1944, internee doctors were attached to blocks. They worked in open blocks, closed blocks, or the *Revier*. In the open blocks, the doctor collected his sick each evening and marched them over to the German *Oberpfleger* (head nurse) at the *Revier*. The *Oberpfleger* decided their fate. Sometimes he sent them to have a paper dressing put on their wounds; sometimes he gave them a mysterious pill and sometimes a thimbleful of wonderful elixir of life. Those with large and dirty ulcers got one to three days off work. A few rare individuals, whose axillary temperature reached 102° F. (38.9° C.), were placed in hospital. Thus the internee doctor in these blocks enjoyed a sinecure. Not so his colleague in the closed blocks. He found himself with large numbers of sick on his hands; he had to dance attendance on the German carpenter, who conducted the sick parade in the block and who amused himself by freely changing diagnoses and treatments, and he had to engage in never-ending disputes with Germans of all grades to procure the tiniest concession for his patients. For the doctor working in the *Revier* the greatest annoyance was the German orderly, who reigned supreme there. The orderly arranged everything; the doctor was his unwelcome assistant, whose most important task was to keep a chart recording the pulse rate, the diagnosis, and the presence of any gold teeth (for reference after the patient's death). The giving of diets or drugs depended on the favour of the internee orderlies, who conducted a black market in everything.

The lack of sufficient drugs made it necessary to treat only the moderately sick, since the more serious would die anyway and the slightly sick would recover.

Pathology of the Internee

Among the many factors influencing mortality in Dachau—starvation, overcrowding, thirst, fatigue, cold, ill treatment—only the first two will be considered at length here.

* An abridged translation from the French.

(a) Starvation

The chief dietary deficiencies were in calories, proteins, mineral salts, and vitamins. The first manifestation of starvation was *loss of weight*—the disappearance of fat leading to the scaphoid abdomen and the sunken orbits of the internee; later came muscle atrophy, the deltoids going first, then the quadriceps and the thigh adductors, so that one could introduce both fists between the adducted thighs, next the gastrocnemii, and lastly the glutei. The skin became dry, hard, wrinkled, and an earthy grey in colour. The hair fell out and the nails became dull, ridged, and brittle.

Parallel with the loss in weight went a progressive cardiac insufficiency. The pulse grew weaker and slower, with lowered tension and smaller amplitude. This bradycardia was interrupted by extreme and prolonged tachycardia on the slightest exertion. On screening, the heart-beats seemed of poor amplitude and the cardiac shadow enormous, clear-cut against the unusually transparent ribs. From the neuromuscular standpoint, reflexes and tonus were diminished; and the slow, clumsy movements of the patient conjured up the memory of a slow-motion film. Eventually came the stage of the living mummy, known in the camp as a "musulman."

But this state of affairs remained for a long time reversible by improved feeding, and even the extreme cases were often an "unconscionable time a-dying," while newcomers to the camp were galloping to their grave. However, the general rule was that after a loss of weight of 50% the changes became irreversible, and the "musulman" died quite suddenly, in his sleep or perhaps at roll-call. The findings at necropsy were atrophied viscera, a small, flabby heart, a pale liver, a dilated stomach with smooth mucosa, and an intestinal wall the thickness of cigarette paper.

To complicate this picture in 80% of cases there was *oedema* and then *diarrhoea*. Oedema was often the first sign of serious trouble. It appeared quite suddenly in ankles and face, and indicated a grave metabolic upset. Frequently the onset was heralded by a spell of nocturnal frequency of micturition. (Such a spell was usually followed within a week or two by oedema, by diarrhoea, or by an aggravation of general weakness.) Usually the oedema increased, involving successively the dorsum of the feet, the legs, the thighs, and the lumbar region, the soft, pale, swollen lower half of the body contrasting with the emaciated thorax and arms. There was a similarity between the face of a victim and that of a myxoedematous subject, a similarity heightened by the bradycardia, hypothermia, apathy, loss of hair, and condition of the skin. But, unlike myxoedema, this oedema pitted and was very labile. A few days of rest in bed made it disappear (with accompanying polyuria), only to reappear on exertion. Withholding fluids had no effect on it.

In time, in addition to the oedema there was pleural effusion, ascites, or acute oedema of the lung. The patient died of cardiac failure or of intercurrent infection, especially pulmonary. Cardiac insufficiency was first thought to be responsible for this oedema, but digitalis was without effect. A renal origin was negated by the absence of urinary abnormalities and by the normal blood urea and lowered blood pressure. The oedema was apparently due to protein lack, its incidence diminishing in times of better feeding and rising sharply when rations were cut. Laboratory tests showed a lowered serum globulin, with increase in the ratio of albumin to globulin.

Diarrhoea often completed the picture of starvation. The stools were liquid, pale yellow, scarcely faeculent, increasing in frequency up to 20–30 a day, and often accompanied by a constant desire to defaecate. The patient also passed mucomembranous material. Within a couple of days his oedema disappeared and his body became skin and bone. His corpse-like face, with dull cornea, dilated pupil, and wide-open mouth, and his flexed, immobile, icy body, from which came a rare superficial respiration, bore mute testimony to his misery. The end usually came within two days.

Besides these cases there was a type of *primary diarrhoea* occurring in patients still in good general condition, which swept through whole blocks, was accompanied by no other symptoms—no rise in temperature, no pathogens in the stools—and failed to respond to all drug treatment, including emetine, sulphonamides, and pentavalent arsenicals. It was at first

thought that normal saprophytic bacteria had become pathogenic. Simple dieting for 48 hours would arrest the complaint at its onset, but a relapse was easily provoked by fatigue, cold, or too speedy return to a normal diet. Cases in a later stage were irreversible and patients died in a state of collapse. This "epidemic" appeared at the same time as the increase in cases of oedema due to the cut in rations, and would seem also to have been a direct result of protein deficiency. Intravenous infusions of normal saline or of hypertonic salt solution (up to 60 ml. of 30% solution daily) given to combat dehydration were useless. After the liberation subjects were given intravenous atropine solution (0.25–0.5 mg.) and were cured completely after three injections. A third form of diarrhoea appeared during an epidemic of *typhus* at Dachau, the co-existence of these types complicating the picture considerably. Often a case which had been regarded merely as obstinate diarrhoea was found to give a positive Weil-Felix reaction. Such cases, which were regarded as an enteric form of typhus, at one time caused many deaths in Block 21, only 300 of a total of 1,600 internees remaining alive there.

Another important manifestation of starvation was *hypoglycaemia*. No one ever saw an acute hypoglycaemic reaction, but in the cachectic cases many symptoms and signs (psychic disturbances, torpor, somnolence, bradypnoea, etc.) recalled the onset of hypoglycaemic coma. The results of blood sugar and C.S.F. sugar examinations (made after the subjects were liberated) in 39 cases of psychosis with cachexia showed on the average:

Blood sugar: 58.8 mg. per 100 ml. (normal, 75–125 mg.).

Sugar in C.S.F.: 62.2 mg. (normal, 50–80 mg.).

Ratio $\frac{\text{sugar in C.S.F.}}{\text{blood sugar}} = 1.095$ (normal 0.52–0.66).

In acute hypoglycaemia the onset of convulsions with a blood sugar lower than 45 mg. per 100 ml. may be explained by the simultaneous fall in C.S.F. sugar to 15–25 mg., whereas in the chronic cases described here no convulsions occurred because some mechanism unknown maintained the level of sugar in the cerebrospinal fluid.

Psychic disturbances were not lacking among the internees. Apart from a general weakening of intellect, growing apathy, and melancholia, cases of hallucination and delirium occurred. In one type of psychosis the prognosis was especially bad; the patient's entire waking hours were devoted to thinking of and searching for food; when he was given his food he played with it interminably, but was incapable of swallowing the least morsel. The commonest *nervous symptoms* were due to a polyneuritis presumably caused by vitamin B deficiency. One patient woke in the morning with bilateral extensor paralysis of the wrists, another had peroneal palsy, and a third became suddenly completely paralysed in both legs but recovered fully after treatment with vitamin B. Nevertheless, vitamin deficiency seemed to play a very secondary part in the camp illnesses. No case of scurvy was found; osteopathies were not frequent, though dental caries was rampant. Xerophthalmia was never seen, but lack of vitamin A may have contributed to the numerous skin affections. Amenorrhoea was common in females, as was a total loss of sexual desire in the males. Azospermia has been found in several patients since their repatriation. *Skin infections* of all grades, from sycosis barbae to phagedaena, were frequent. Furuncles were often seen, and were very slow in healing; carbuncles were remarkable for their extent and indolence, and the lack of accompanying fever. Giant pemphigus occurred often on the hands. Large abscesses formed and tracked along muscles and tendons, but caused little pain, no local heat, and no temperature rise: all these lesions were slow in cicatrizing.

Lung affections were common, starvation and cold both helping to produce them. Of deaths in winter 40% were due to pneumonia (case mortality 25%). Pneumococcal empyema was a frequent complication, with a mortality of 75%. The most interesting pulmonary affection was *tuberculosis*, 40% of necropsies showing tuberculous lesions and 15% of returned internees having some radiological evidence of the disease. Its incidence was much more closely related to diet than to overcrowding, some favoured internees in Block 16, with a dietary far above the average, being practically free from it. All the clinical types were to be seen. Acute forms appeared as

caseating pneumonia during periods of extreme cold and as miliary tuberculosis under the spur of typhus, but the characteristic form at Dachau developed slowly, was usually bilateral, and radiologically had a floccular appearance. So slowly did it develop among the really cachectic that they did not appear to die any sooner than those with simple cachexia. Pleural effusions were very common, and some were even cured, *mirabile dictu!* On the whole it was surprising that not more than an average of 20% of the internees in each block died from tuberculosis.

(b) Overcrowding

In the closed blocks at Dachau 400 men occupied a room of some 200 cubic metres capacity. In such a place all the normal acts of life become a source of misery, and to the doctor who must look for, examine, and treat the many sick in this chaos the adequate exercise of his profession becomes impossible. Morbidity and mortality were seen to vary with the degree of overcrowding. (With 525 in one block, mortality was 3.4% a month; with 1,350 in it, the monthly mortality rose to 10%.) An early result of overcrowding was the appearance of *scabies*, often with secondary infection. *Erysipelas* of the face was also widespread; there were frequent relapses due to poor hygiene measures, but the prognosis was fairly good. Treatment was by sulphanilamide.

The most important epidemic disease in the camp was *typhus*. At Dachau this disease had an average incubation period of 14 days. After a pseudo-influenzal period of invasion of 2 days the characteristic picture appeared. The diagnostic signs were: (a) intense headache, with tinnitus and deafness; (b) ataxia, accompanied by a pathognomonic drunken gait; (c) a conjunctival hyperaemia, which appeared before the fever; (d) a temperature of 102–104° F. (38.9–40° C.), with a very rapid pulse. In addition, intense lumbago was usual. On examination a mild splenomegaly and signs of congestion at the bases of the lungs were practically constant. An interesting sign, diagnostic even in convalescents, was the appearance of rapid localized contraction on pinching the biceps. The rash, discrete and dark red, appeared on the fifth or sixth day on the trunk and the anterior aspect of the arms. This state of affairs lasted 12 to 14 days, with anorexia, photophobia, and oliguria. The temperature oscillated between 102° and 104° F. with an almost regular drop every third or fourth day. Half of the deaths were due to circulatory failure, lowered blood pressure (average 90/50) and tachycardia being usual. In patients recovering, the fall in temperature might be by crisis or by lysis. Convalescence was very prolonged, with asthenia and signs of cardiac weakness. At any stage of the illness complications might occur; these comprised three clinical types: (a) gastro-intestinal, with diarrhoea as the chief symptom (20% of fatal cases); (b) pulmonary, with bronchopneumonia, pleural effusion, or a miliary spread of pre-existing tuberculosis; (c) nervous—the most interesting form. Apart from the headache and photophobia indicating meningeal complications, and the ataxia of cerebellar origin, other signs of involvement of the nervous system were psychic disturbances, hallucinations, delirium, convulsions, mania, opisthotonos—all of grave prognostic import and often the only features of the case apart from extremely high fever. In convalescence, even 10 to 15 days after defervescence, palsies and paraesthesiae appeared and the intellect was usually weakened. Among complications, otitis media, mastoiditis, parotitis, and phlebitis may be mentioned; but the constant myocardial involvement which left the patient incapable of effort for long periods afterwards must be particularly stressed. It was observed that the epidemic, which at first had a case mortality of 80%, gradually became attenuated and finally left behind a trail of mild cases, among which even the cachectic recovered.

The western Europeans were much more severely attacked than the Slavs, and men in good condition underwent more rapid and severe forms of illness than did the cachectic. The main factor determining survival was age—the older the subject the less his chance. Although lice were universal, 20% of the inmates never showed clinical signs of the disease (? ambulant cases, ? naturally immune). Most of the patients had no treatment; the lucky few who were placed in hospital did well on intravenous glucose-saline and cardiac tonics. Towards the end

of the epidemic an attempt was made to treat early cases with transfusions (200–250 ml.) of convalescent blood. The method appeared efficacious, but its correct evaluation was almost impossible.

It is unnecessary to dwell on the brutalities practised at Dachau, or on the alleged experiments carried out there, which cost the lives of hundreds of internees and were almost totally without scientific value. But it can be stated that the epidemic of typhus, which began on Dec. 17, 1944, with one case, was due entirely to the wilful negligence of the S.S. medical personnel, who encouraged its spread by distributing contacts freely about the camp.

Medical Sequelae of Dachau

Of the returned internees, 65% were found to be ill, in contrast with 7.7% of prisoners of war. Moreover, 30% were still ill in March, 1946, ten months after their liberation. The most important sequel was lung impairment, which was found in 25.8% of returned internees. Pulmonary tuberculosis occurred in 16.7%. Cardiac impairment was present in 3%, of whom one-quarter died within a year. Digestive disturbances were still present in 2.1% in March, 1946, but in general were not severe. After liberation a number of internees developed gastric ulcers—an almost unknown disease at Dachau.

Avitaminoses were rare and disappeared rapidly, but cachexia and oedema were troublesome and slow to disappear, as was the tendency of the skin to infection. Almost all the internees maintained a sympathetic hyperactivity (e.g., sweating on the slightest exertion) for at least six months after their return; concentration was difficult, memory was impaired, and there was irritability and instability.

JOINT TUBERCULOSIS COUNCIL

At the last meeting of the Joint Tuberculosis Council tribute was paid to the late Dr. George Jessel, who was vice-chairman at the time of his death. Dr. James Boyd, Chief Medical Officer, Ministry of Health and Local Government of Northern Ireland, attended as observer on behalf of his Ministry, and was cordially welcomed. The Council adopted a report prepared by a committee on the re-definition of terms used in tuberculosis work. The report suggested the abolition of the present system of recording cases, and suggested new classifications. New definitions of "quiescent," "arrested," and other terms were also suggested. The report was forwarded to the Minister of Health with a request that its recommendations be carried into effect.

Attention was drawn to the anomaly created by a recent ruling that where family allowances under the Government scheme are received by persons who are entitled to financial assistance under Memorandum 266/T, the 266/T allowances must be reduced by the amount of family allowance received, and the Council authorized a deputation to express to the Ministry the strong view that family allowances should have no effect upon allowances granted to tuberculous persons as such. The question of bread rationing and its effects, if any, upon tuberculous persons in and out of sanatoria was referred to the Council's committee on nutrition. Arising out of resolutions adopted at a previous meeting expressing alarm at the probable effect of the National Health Service Bill on the tuberculosis service, it was reported that a deputation representing the Joint Tuberculosis Council and the N.A.P.T. had met Sir Wilson Jameson. Sir Wilson on that occasion said that there was no intention to detach preventive work from curative work. He had also given assurances on other points. The report of the interview was accepted without prejudice to any future action which the J.T.C. might consider necessary in relation to the Bill. The standardization of the forms of record used by local authorities in connexion with their tuberculosis services was discussed, and a committee was asked to consider the present situation and, if possible, to suggest standard forms for universal use.

Arising out of a resolution of the Tuberculosis Association, the Council appointed a special committee to consider the establishment of a Bureau of Tuberculosis Statistics. The new committee was empowered to explore the possibilities of collecting tuberculosis morbidity statistics, to plan statistical inquiries into selected problems, and to advise—or arrange for expert advice to be afforded—on the collection of data. The committee was made as representative as possible, its membership including a tuberculosis officer, a sanatorium superintendent, a thoracic surgeon, an orthopaedic surgeon, a paediatrician, a radiologist, a bacteriologist, and a medical officer of health. The Council decided to approach the Nuffield Foundation for assistance in the project.

RESULTS OF THE PLEBISCITE

Table I shows the returns received up to midday, Dec. 16. The classification is according to the professional group and the number of years since qualification.

Table I.—Those Qualified 0-14 Years

Further Analysis

In Categories 1 to 14 of those to whom voting papers have been sent up to 12 noon on Monday, Dec. 16, 81% have replied; 37% have voted Yes; 44% have voted No; and 19% have not replied. Of those who have voted 46% have voted Yes and 54% have voted No.

Tables I and II do not include voters in the Services.

Up to Dec. 16 the proportion of Service practitioners who have sent in their voting papers is approximately 34%. Of those who have voted 56% have voted Yes and 44% have voted No.

In England and Wales only, of those in Groups 1 to 14 to whom voting papers were sent, 83% have replied: 38% voted Yes; 45% voted No; and 17% have not replied. That is, of those voting 46% voted Yes and 54% No. Categories 1 to 4

include consultants and specialists, general practitioners, whether principals or assistants, and whole-time voluntary hospital staff. In Great Britain of those to whom voting papers were sent 92% have replied: 37% voted Yes; 55% voted No; and 8% have not replied. Of those who have voted, 41% voted Yes and 59% No. In England and Wales only, 93% of Categories 1 to 4 have replied: 38% voted Yes; 55% voted No; and 7% have not replied. Again, of those who have voted 41% voted Yes and 59% No. Of general practitioners, principals and assistants, in Great Britain, 88% have replied: 32% voted Yes; 56% voted No; and 12% have not replied. In England and Wales only, 90% replied: 32% voted Yes; 58% voted No; and 10% have not replied. In each case of those who have voted 36% voted Yes and 64% No. A final report on the plebiscite, embodying civilian and Service figures, will be made soon after Jan. 6.

COUNCIL'S DECISION ON THE HEALTH ACT

STATEMENT BY DR. DAIN

The following statement was issued to the Press on Dec. 12 by the Chairman of Council, Dr. H. Guy Dain.

As everyone knows, the medical profession has stated plainly through its Negotiating Committee that the National Health Service Act as passed is in conflict with the principles of the profession. That was the position before the plebiscite was taken. The question posed to the profession by the plebiscite was "Shall we or shall we not enter into any discussions on the framework to be created within the limitations of that Act?" The results of the plebiscite are now known. The Council of the British Medical Association met yesterday to examine the results. The question it plainly had to consider was whether there was a majority and, if so, whether it was a sufficient majority to justify not entering into discussions with the Minister. The Council's answer to both these questions is in the affirmative. It decided to call a Special Meeting of the Representative Body on Jan. 28 next to consider the results of the plebiscite and to approve the following resolution:

Resolved.—That the Negotiating Committee be advised that in view of the results of the plebiscite the Minister be informed that because of the divergence between the principles of the profession and the provisions of the National Health Service Act, the Committee is unable to enter into discussions with the Minister on the Regulations to be made under that Act.

This followed a discussion on the result of the plebiscite, which was presented in such detail as to enable the attitude of every branch of the profession to be assessed.

It was at once apparent that of the doctors mainly concerned—i.e., the general practitioners, 64% had voted against negotiating. As was to be expected, this situation was reversed in the case of men already in whole-time salaried appointments, though the large proportion of those actually in Government service voting against negotiation was regarded as significant.

The poll of civilian doctors was just over 80%, an extraordinary response comparing more than favourably, for example, with the poll at the last two General Elections. Of this, 54% were "No" and 46% "Yes." The Service poll was inevitably small, on account of distance and difficulty of tracing units, only 32% replies being received to date. Of these 56.3% voted "Yes" and 43.7% voted "No."

An examination of the analysis shows a consistent picture all the way through. In the general practitioner group the young doctors effectively support the majority against negotiation. There is no question of age overweighting the decision.

The B.M.A. is a democratic body and in the light of these figures the Council has no mandate to negotiate.

The position therefore is that the B.M.A. is not empowered to accept any invitation that may be given by the Minister to the medical profession to join him in discussing the regulations to be made under the National Health Service Act. He may have many offers of help, but none from the main body representing the profession.

It is important to remember that the National Health Service Act is not a Conscription Act and that a decision not to join the Service is not disloyalty to the country. Whatever the ultimate outcome the doctors will be loyal to their calling and to their patients, to whom, as always, they owe their first duty.

STATEMENT BY THE MINISTER PLEA FOR "WISER COUNSELS"

After the announcement of the result of the plebiscite the following statement was issued by the Ministry of Health on Dec. 12:

"The Minister has learnt that the B.M.A. are placing the results of the plebiscite before a Special Representative Meeting with a recommendation that the profession should refuse to discuss with him the steps to be taken to bring the National Health Service Act into operation. He hopes that before any final decision is taken accepting this recommendation, wiser counsels will have prevailed; and he feels sure that the medical profession will take no steps which would make it difficult for them to take part in the comprehensive Health Service which the people of this country so ardently desire.

"Meanwhile, the Minister has a clear duty to carry out the instructions of Parliament as expressed in the Act, and he can no longer postpone the consultations which are a necessary preliminary to the setting up of the administrative machinery. He is, therefore, proceeding to consult all the many other interests which will be concerned in the National Health Service. He is also considering what ought to be done—and this is a matter to which he attaches great importance—to give the medical profession the opportunity of assisting to shape, and of playing its part in, the new Service."

CLASSIFYING CAUSES OF DEATH MEDICAL ADVISORY COMMITTEE

The Registrar-General announces that in connexion with the revision in 1948 of the International List of Causes of Death, the Minister of Health has appointed a Medical Advisory Committee "to consider from the medical point of view and to advise upon the alterations to be suggested by H.M. Government in the United Kingdom at the forthcoming revision of the International List of Causes of Death."

Sir Ernest Rock-Carling, F.R.C.S., Dean of Westminster Hospital Medical School, is chairman of the committee, of which the following are members: A. W. M. Ellis, D.M., F.R.C.P., Regius Professor of Medicine, Oxford University; Charles F. Harris, M.D., F.R.C.P., Dean of the Medical College, St. Bartholomew's Hospital; Aubrey J. Lewis, M.D., F.R.C.P., Professor of Psychiatry, London University; A. H. T. Robb-Smith, M.D., Nuffield Reader in Pathology, Oxford University; Eardley Holland, M.D., F.R.C.P., F.R.C.S., late President, Royal College of Obstetricians and Gynaecologists; N. Hamilton Fairley, M.D., F.R.C.P., F.R.S., Wellcome Professor of Tropical Medicine, London University; A. Bradford Hill, D.Sc., Ph.D., Professor of Medical Statistics, London University; Percy Stocks, M.D., D.P.H., Medical Statistician, General Register Office and Ministry of Health; Melville Mackenzie, M.D., D.P.H., Principal Medical Officer, Ministry of Health; Sydney Smith, M.D., F.R.C.P.Ed., Regius Professor of Forensic Medicine, Edinburgh University; W. W. D. Thomson, M.D., F.R.C.P., Professor of Medicine, Queen's University, Belfast. The secretary of the committee is Mr. L. M. Feery, of the General Register Office.

Recognition of the importance to medical research of internationally comparable statistics of causes of death inspired the formulation of the present classification, which was first adopted by the International Institute of Statistics in 1893, and which has been revised on five occasions by an International Conference convened decennially since 1900 by the French Government. The main achievements of the conference have been to revise the terminology of the International List of Causes of Death in accordance with scientific developments, and to initiate the agreement relating to statistics of causes of death signed in 1934 on behalf of over 20 Governments, which undertook to compile and publish their statistics according to the agreed International List. Provision has now been made for the next revision of the International List of Causes of Death (which is due to be made in 1948) and the establishment of an international nomenclature of diseases to be carried out under the auspices of the World Health Organization.

Health identity cards will be issued to all French babies born in 1947 and thereafter, and will follow their owners throughout their lives. Free medical examinations will keep them up to date.

THE TEACHING OF DERMATOLOGY

The treatment of skin conditions forms so large a part of general and hospital practice and is of such importance to industry, where many of these conditions are acquired, that the Royal College of Physicians of London last year appointed a committee to consider the education both of undergraduates and of postgraduates in this subject and the establishment of a comprehensive dermatological service. The committee, of which Lord Moran was chairman and Dr. Henry MacCormac vice-chairman, issued an interim report last January dealing mainly with the latter part of its terms of reference. Its final report is concerned with the subject of teaching.

The committee suggests ways in which the study of dermatology might be integrated within a planned medical training, beginning in the preliminary year with some reference to the common parasites as part of the study in biology. In physiology the importance of the skin in the preservation of health should be emphasized. In the introductory course recommended by the Goodenough Committee to illustrate principles of general medicine, surgery, and pathology, lesions of the skin, which are so directly observable, should provide a suitable medium. During the period of systematic instruction in general medicine, introductory instruction in the principles of dermatology should be given as part of the course. It is recommended that the student's appointment in dermatology should cover a period of three months, with attendance at least twice a week as clinical clerk to in-patients and out-patients. A departmental examination in dermatology should be held before the final. A sufficient proportion of beds for dermatological cases should be allocated: 5% of the total beds in a teaching centre is suggested.

Training the Consultant

The proposed dermatological institute in London would be an important step towards the development of postgraduate dermatological education of the desired standard, and one which, in the view of the committee, should be followed in other regions. There are three groups for which provision for instruction in dermatology should be made: (1) intending consultants in the subject, (2) intending dermatological specialists, and (3) practitioners attending refresher courses. For consultants in dermatology the committee recommends a period of five years' study after registration, this training to include: an appointment in the department of general medicine for a year, and in the pathological and bacteriological departments for a year; the study of actinotherapy, radiotherapy, venereal diseases, fevers, and industrial medicine; clinical work as an assistant or registrar in the dermatological department of the teaching institution; and a period of study abroad. For dermatological specialists a short-term policy would be to fill vacancies in the non-teaching hospitals with graduates who for a reasonable time have been practising the specialty and have held hospital appointments in dermatological departments. The long-term policy should be the provision of properly trained dermatologists to staff all the hospital regions.

It is considered that graduates who wish to be recognized as consultants in dermatology should be required to obtain a university degree and a diploma or degree comparable to the M.R.C.P. Some universities have already instituted an M.D. in dermatology. It is not thought desirable at present to recommend the establishment of a diploma in dermatology, but it is recommended that the Royal College should set up a dermatological board for the recognition of hospitals at which postgraduate training could be undertaken, for the laying down of standards of training, and for advice on the suitability of candidates for appointment to hospital staffs.

Future Needs

In its earlier interim report the committee discussed the number of dermatologists likely to be required in a National Health Service. It endorses the conclusion given in a memorandum which was laid before it by Sir Archibald Gray that 180 whole-time dermatologists in charge of clinics would be needed in Great Britain. This is on the basis of four per million population. If, as was suggested in the recent Hospital Survey of the London Region, a general hospital of 600-700 beds for acute cases (or of 950-1,000 if chronic and infectious

cases are included) is required for a population of 125,000, it would mean 360 such hospitals, so that there would be one dermatologist to every two hospitals. In addition the teaching hospitals would each require another two dermatologists of consultant status, making a further fifty. At present there are believed to be 85 part-time dermatologists of consulting-rank in active work in Great Britain, and some twenty or thirty doctors in charge of skin clinics who are either general physicians or general practitioners. If all these were put on a whole-time basis the number available would be 115. This number therefore will have to be doubled to meet the requirements of a comprehensive dermatological scheme. If some of these dermatologists in charge of departments or clinics continued in private practice—which the committee does not exclude—a further increase would be necessary in proportion to the number undertaking only part-time employment.

Nova et Vetera

"OLLIER" OR "THIERSCH" SKIN GRAFTS

French authors attribute the free split-skin graft to Ollier, of Lyons, and reproach English and American surgeons for erroneously describing this particular variety of graft as the Thiersch graft. It is of interest to read Ollier's original communication.

Ollier's Communication

At a meeting on April 2, 1872, Dr. Ollier, of Lyons, reported on autoplasmic skin grafts and subperiosteal resection of the scapulo-humeral articulation. The following is a literal translation of the communication:

Autoplasmic Skin Grafts.—In place of grafting small portions of epidermis, 2, 3, or 4 mm. in diameter, as Reverdin did, Ollier grafts large strips, 4, 6, or 8 cm. square or larger, which comprise not only the superficial layers of the skin but also the whole thickness of the dermis. His aim is not to create multiple centres of epidermization but to replace the epidermic pellicule of ordinary scars by a membrane with the essential elements of normal skin in regard to both structure and function.

The scar obtained by sowing little shreds of epidermis on the surface of a wound does not differ from ordinary scar tissue. Epidermization of the granulations is more or less hastened, but the process is the same. It operates by transforming, step by step, the most superficial layer of the fleshy granulations into epidermis. Ollier considers that the connective tissue of the dermis plays the principal part in skin grafts, and, to show that the connective tissue is able to graft itself, he cites a case in which 20 days ago he grafted periosteum on to the surface of a healing ulcer. He spread over the granulations a strip of periosteum, 6 cm. square, taken from a leg he had just amputated. This is the first time he has transplanted periosteum in man under those conditions, and he is not yet able to say what the result will be as regards the osteogenic properties of the transplant. Ollier has not been able to study the late changes of these dermo-epidermic grafts. He has been using strips, which include part of the dermis, for two years, but his experiences with the large grafts of whole thickness skin are still too recent to enable him to describe the late results.

He has employed the dermo-epidermic grafts to maintain separation of the fingers after an operation for syndactyly caused by an extensive burn of the hand. He has also used them to cure old scars, interrupting, by means of the transplanted tissue, the continuity of the scar tissue. A year later the graft was recognizable by its greater suppleness and by its colour, which stood out against the violet base of the scar. It seemed to him, however, that the results would be more complete and lasting if the whole thickness of the dermis were transplanted, as is his present practice.

In order to oppose cicatricial retraction by means of a skin graft one must not rest content with applying the strip to the excoriated or revived scar, but the infiltrated tissue must be excised and the dermis grafted on to the underlying sound tissues as soon as the layer of granulations has formed. The infiltrated tissues must not be covered, they must be replaced: then only will the graft be a truly autoplasmic proceeding, which will be applicable when a sliding autoplasty cannot be used because of the extent or position of the scar.

Ollier procures his skin grafts either from the patient himself or from limbs amputated after injury in healthy subjects. When taken from the patient the part may be congealed by a freezing mixture.

Ollier has, in the past, been able to obtain bony tissue with flaps of periosteum from animals which had died less than twenty-four

Vitamins in diseases of the mouth

Unhealthy oral conditions may result from dietary deficiencies. Appropriate correction of such deficiencies at an early stage may prevent the development of more serious conditions.

VITAMIN A deficiency This may cause hyperkeratosis of the gums as well as over-growth of epithelia elsewhere. It causes hypoplasia of the enamel organ in experimental animals and there is evidence that vitamin E deficiency has a somewhat similar effect.

VITAMIN D deficiency This affects the developing enamel, dentine and alveolar bone. Calcium deficiency aggravates its effects.

VITAMIN B₁ deficiency Small herpetiform vesicles may appear under the tongue or on the palate. They clear up quickly on vitamin B₁ treatment.

BIOTIN deficiency This produces cheilosis and a magenta-coloured glossitis, unaccompanied by gingivitis (unless this arises from other causes).

NICOTINIC ACID deficiency The specific glossitis is fiery red and painful. Gingivitis characteristically accompanies it (contrast riboflavin deficiency) also generalised symptoms—weakness, lassitude, insomnia, headache.

ASCORBIC ACID deficiency Hyperaemia occurs with swelling of the interdental and marginal regions of the gums which are tender and bleed easily. The gingivitis though not directly due to the deficiency usually responds to ascorbic acid administration.

Further particulars of the various vitamin products available for the above conditions are obtainable on request from

Vitamins Limited

THE INTRAVAGINAL TAMPON

*in Menstrual Hygiene
minimizes the risk of infection*

THE correct position of the internal tampon avoids contact with both anal and urethral sources of contamination. Tampax tampons are simply and hygienically inserted in correct proximity to the cervix by means of a disposable 'applicator' tube, only $\frac{1}{8}$ " in diameter. The function of the applicator in inserting the tampon at the upper end of the vaginal tract is of the greatest importance. It eliminates any handling of the highly-compressed soft surgical cotton, and ensures comfort and steady absorption. Tampax tampons are easily removed and disposed of, by means of a moisture-proof cord 'built into' the tampon in its first stage of manufacture, proof also against any risk of disintegration. The positive 'wick' action of the surgical cotton obviates any blocking of the flow.

Tampax may confidently be recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymenal aperture would cause difficulty in insertion and withdrawal.

PHARMACEUTICAL SPECIALITIES (MAY & BAKER) LTD., DAGENHAM

AURO-CALCIUM

Gold therapy now takes a foremost place in the treatment of rheumatoid arthritis. Toxicity, formerly of sufficient severity to detract from its general usage, has been materially reduced by a more careful selection and management of cases, a much lower scale of dosage, and the development of less toxic gold salts.

Crookes Auro-Calcium, a finely divided aqueous suspension of calcium aurothiomalate, provides an appreciable contribution to this reduction of toxic effects.

CROOKES
AURO-CALCIUM

*Available in single ampoules
and in boxes of six ampoules.*

*Strengths:
10 mg. 25 mg. 50 mg. 100 mg.*

THE CROOKES LABORATORIES LIMITED
PARK ROYAL LONDON, N.W.10

Peptic Ulcer and hypovitaminosis C

It has been shown experimentally that there exists a relation between peptic ulcer and hypovitaminosis C. Clinically it has been found that a considerable proportion of patients with low vitamin C reserves suffered from gastric or duodenal ulcer. Whether lowered vitamin C intake due to restricted dietary is always the cause of hypovitaminosis, or whether the hypovitaminosis is an ætiological factor in ulcer formation, is not yet determined.

Tests at various hospitals, employing two to three fluid ounces of 'Ribena' Blackcurrant Syrup daily, clearly showed that in acute cases of peptic ulcer, or cases of fairly recent standing, the supplement of blackcurrant juice accelerated disappearance of symptoms and of X-ray evidence of ulcer. Cases of hæmatemesis did particularly well on 'Ribena' therapy.

Ribena
BLACKCURRANT SYRUP

(Not less than 20 mg. ascorbic acid per fl. oz.)

Thermega
MEDICAL APPLIANCES

made by the Pioneers of electrically-heated blankets in the U.K., are approved and used by the ADMIRALTY, AIR MINISTRY and leading HOSPITALS

RELIABILITY

Best quality materials and workmanship. GUARANTEED for twelve months, but will last for years. DOUBLE PROTECTION.

"Thermega" medical blankets have two independent thermostats, each operating in a vacuum, ensuring (1) constant temperature; (2) safety near volatile gases.

SERVICE

Periodical visits to medical institutions are made (free of charge) for inspection of Thermega equipment.

Write for descriptive booklet No. 52 which illustrates BLANKETS, Ward, Operating Theatre, Ambulance and Accident Reception.

CAGE HEATERS for Limbs, Prematurely-born babies, etc.

PADS, for local application. Specially designed appliances for Ear, Eye, Head and other purposes.

"THERMEGA" is the accepted standard for electrically heated Medical Equipment

RATIONAL THERAPY
BUCCO-PHARYNGEAL
INFECTIONS

The Twenty-Lozenge Pack

Penicillin Lozenges A & H are issued in glass tubes to prevent inactivation of the penicillin by atmospheric moisture.

The number of lozenges contained in the tube (TWENTY) provides the most suitable package to meet the needs of individual treatment prescribed by the physician. Not only does it tend to eliminate waste but it assures the prescriber that the lozenges will not have time to become inactivated by exposure to a moist atmosphere before the prescribed treatment is completed.

Penicillin Lozenges A & H are indicated for the effective local treatment of bucco-pharyngeal infections.

In tubes of 20 Lozenges.

PENICILLIN LOZENGES A & H

ALLEN & HANBURYS LTD. LONDON E.2

hours previously and which had been kept at several degrees below zero. Without being able, at present, to establish the extreme limits of vitality of pieces of skin, he believes that the conditions are approximately analogous with those determined for periosteal grafts.

To ensure success of the grafts the region operated on must be immobilized by means of a silicate bandage, or by any other means which will completely prevent any movement of the region and any shifting of the graft on the wound. The silica dressing has not only the advantage of securing immobilization but also maintains the graft in a constant environment as regards temperature and humidity. This favours adhesion.

The coloured plates exhibited at the meeting show the appearance of the grafts, their size, and the modifications they effect on the composition of the scar. One of the plates shows that the portions of skin (detached after being congealed by means of a freezing mixture) forty-five days after grafting are completely different in colour from the violet base of the remainder of the scar which had been formed by the ordinary healing process.

Thiersch's Paper

Let us next consider Thiersch's (1874) original paper, "Concerning the Detailed Changes when Skin is Grafted on to Granulations." It is too long to reproduce *in extenso*, but the following extracts, which give its substance, support the contention of French authors that Ollier discovered the method and that the only contribution made by Thiersch was the suggestion that the granulations should be shaved down before applying the grafts.

Thiersch speaks of having used Reverdin's method with success, and goes on to record that he had recently used one of the various modifications for experimental grafting of a leg ulcer before amputation. "Squares of whole skin, 1 cm. across, separating the fatty layer with great care," were grafted at intervals during three weeks, the last 18 hours before operation. After amputation, sections of the grafted area were cut, and he concluded that successful anastomosis between the capillaries of the bed and the graft were already established after 18 hours, because he was able to inject the capillaries of the graft through the vessels of the granulating area. He goes on to say, "Good material to cover the granulating area can always be found at the edge. One takes, with a razor, thin flat slices and transfers them to anywhere on the area. The gaps caused at the edge close in two to three days." He points out that Reverdin's method of grafting on to granulations may fail, and suggests that the superficial layer of granulations should be shaved down to leave the deeper layer which consists of fine connective tissue with a horizontal network of vessels, so that the skin may be implanted on to this firm deeper layer. "My investigations are not complete and it may be necessary to wait longer than just till bleeding has ceased; perhaps a few hours should elapse, during which time, under the protection of a Lister dressing, the first stages of an inflammatory reaction have set in. By this method it may perhaps become possible to attain the desired permanency of skin cover."

It therefore seems obvious that Ollier initiated the split-skin strip graft, and his name rather than that of Thiersch should be associated with it. It further appears that Ollier used, and Thiersch was experimenting with, *whole thickness skin grafts* some years before Wolfe (1875), Surgeon to the Glasgow Ophthalmic Institution, employed this method, though the latter is generally regarded as the discoverer of this particular variety of graft.

Ollier's method of freezing the skin before cutting the graft, and of preserving the graft by freezing it, is of particular interest in view of recent articles (Matthews, 1945; Strumia and Hodge, 1945; Webster, 1944) recommending this method of storing skin grafts.

Reports of Soc

L.C.C. HOSPITAL EXPERIENCE

Hospital usage of penicillin was discussed at L.C.C. Service Medical Society on Nov. 13 with DALEY presiding.

Clinical Pathological Experiences

Dr. J. M. ALSTON said that there was a renewed interest at present in giving the drug by direct local application to lesions available for such procedure. It had been shown that several objections hitherto urged against local use were not valid. The drug was not destroyed when instilled in liquid form into a wound or placed upon it in powder form. Local concentration was, of course, much more lasting after local application than after intramuscular injection, while blood-stream titres were equivalent. The injection or local application of two doses of 100,000 to 200,000 units daily was the aim, and many patients maintained an effective blood concentration for eight hours or more after the larger dose. Penicillin had been least successful in curing chronic infections such as those of bones, cranial sinuses, and skin, and even with this most powerful drug available there was something which the body must do for itself in chronic infections.

Medical Aspects of Penicillin Therapy

Dr. B. A. YOUNG discussed experience gained since April, 1945, in the treatment of 129 cases—including 53 pneumonias, 10 empyemata, 13 carbuncles, and 11 meningitides. Of the pneumonia patients (half of them being over 40 years of age) there was recovery in 38, improvement in 4, no change in 3, and death in 8 (4 were moribund on admission). Up to April, 1946, the usual adult dose was 30,000 units initially by intramuscular injection followed by 15,000 3-hourly doses (120,000 units in 24 hours), but during the past six months the initial dose had been 60,000 units followed by 30,000 units 4-hourly (180,000 units in 24 hours), and now the monthly hospital consumption was between 150 and 200 million units. In cases with a very bad prognosis the dose had been increased to 60,000 units 4-hourly (360,000 units in 24 hours). There was now a growing tendency towards increased dosage at longer intervals, and experiments were being made with doses of 250,000 units, soluble in 1 ml. water, at 8- to 12-hour intervals. Intermittent high blood penicillin levels produced by large infrequent doses were considered in most cases to be as efficient as the constant but lower titres produced by continuous or more frequent penicillin administration.

In the 10 cases of empyema there were 8 recoveries and 2 deaths (one aged 80 and the other complicated by pulmonary tuberculosis). Treatment had been by administration of systemic penicillin in doses of 30,000 to 60,000 units 4-hourly, with repeated aspiration of the fluid and intrapleural injection of 60,000 to 120,000 units of penicillin in 20 to 50 ml. of distilled water on alternate days. In carbuncle 13 cases had been treated, with recovery in all, and the infection responded readily to moderate doses.

The 11 cases of meningitis showed 7 recoveries and 4 deaths. Among these cases were the three of Dr. B. Gottlieb's of *Haemophilus influenzae* meningitis, in which the prognosis is extremely grave: the organism is now recognized as only relatively insensitive to penicillin. The three very young subjects had, in addition to systemic dosage, heroic intrathecal doses of very pure penicillin up to 50,000 units per dose, and complete cure was obtained in two cases. In the third, however, although the cerebrospinal fluid became sterile after the seventh intrathecal injection the organism later reappeared and, despite 27 intrathecal injections, the patient died after nearly three months of continuous treatment. No convincing evidence of the value of systemic penicillin in cases of acute haemorrhagic nephritis had been obtained. The problem which the physician frequently faced in treating meningitis was to decide on the line of action to be taken if a turbid cerebrospinal fluid was withdrawn and no expert bacteriological opinion was immediately available. The introduction of penicillin into the cerebrospinal fluid was not without risk and in meningococcal meningitis

to be unnecessary. The risks were very slight, however, the precautions were taken of using pure penicillin of concentration of 1,660 units per mg. for intrathecal injection of making up each dose separately in a sealed ampoule.

Surgical Conditions

Mr. J. JEMSON stressed certain points in the treatment of acute haematogenous osteomyelitis. A positive blood culture might be the only confirmatory evidence of the clinical diagnosis, and an early case, treated adequately, might never reveal radiologically any bone changes. Incision of abscesses or drilling of bone should not be undertaken until the patient had been safeguarded by at least 24 hours' intensive penicillin therapy—400,000 units in 24 hours. Incisions could be safely closed, or closed around a small tube which was used for local therapy, after operative evacuation of pus with cleaning and dusting of the cavity with penicillin powder, and they healed satisfactorily. Between the sixth and ninth weeks decalcification of the bone was maximal, and it might be necessary to guard against a pathological fracture. A severe case of actinomycosis, with sinuses of the chest and abdominal walls, was treated by large doses of penicillin after all other treatments had failed, and the patient had become emaciated and developed an enlarged liver and spleen. One million units was given daily for thirty-five days, and after six weeks' rest, during which time the patient's condition deteriorated a little, a further course was given of one million units daily for 21 days, and a final course of three million units daily for seven days. The patient improved, all sinuses healed, liver and spleen were palpable, but he later returned because the sinuses had reopened.

Experiences in Other Hospitals

Mr. E. T. BAILEY'S experience in the chronic recurrences of osteomyelitis, which were so frequently met with, was that the infections were not likely to respond to penicillin, even in high dosage, but he had been impressed by the results of local treatment with penicillin.

Mr. G. C. DORLING remarked on the absence of reference to penicillin continuous drip. Some casualties from Normandy had refused to have the three-hourly injections, and continuous drip, which was a painless procedure, was used. In acute osteomyelitis his practice had been to give rest in a padded plaster and systemic penicillin. The temperature usually dropped within two or three days and rose again on the fifth to the seventh day, when he took the plaster off; if there was a periosteal abscess it was opened and incised, dusted with penicillin, and sutured.

Mr. IAIN MATHESON described a case of early osteomyelitis of the fibula in a girl aged 9, which showed that penicillin alone was not curative in these conditions, but it might possibly be better to withhold operation on osteomyelitis of the bones of the foot.

Dr. M. TOOHEY considered that a less good result was obtained with $1\frac{1}{2}$ million units in 24 hours than with three injections of 300,000 units each day, a total dosage of 900,000. Newborn babies with minor skin infections had shown a dramatic response to oral penicillin. There was blood concentration in babies up to therapeutic level with oral penicillin after about 10,000 units 3-hourly in the feeds. Dr. W. WHEATON mentioned unsuccessful treatment of subacute bacterial endocarditis with penicillin doses of a million units a day up to a total, in one case, of nearly 200 million units. Dr. H. LEVY discussed eight cases of erysipeloid, an occupational disease of fishmongers and pork butchers which incapacitated the workers up to three weeks, but those who had had injections of penicillin in beeswax were able to resume their work within one week.

Voluntary self-help by wage earners in the form of payments for hospital services has not, according to the annual report of the Hospital Saving Association, been diminished by the preparations for the National Health Service, for the total sum paid is greater than ever. The distribution to London voluntary hospitals for 1945-6 is £s. for each in-patient day. Since the war the incidence of treatment has risen, partly as a result of more beds becoming available, and if this trend continues the daily rate of contribution to the hospitals will fall, since the H.S.A. donation is fixed. Nearly £14,000,000 has been distributed for hospital services by the H.S.A. in the 24 years of its existence.

Correspondence

Surgeons Up in Arms

SIR,—The *Daily Telegraph*, dated Dec. 2, says: "Surgeons and Health Act.—The Council of the Royal College of Surgeons have asked the negotiating committee to enter into negotiations with the Minister of Health on the regulations authorized by the National Health Service Act." At a special meeting of Fellows and Members held at the Royal College of Surgeons on Nov. 29 (*Journal*, Dec. 7, p. 869), the President, Sir Alfred Webb-Johnson, in refusing to allow certain resolutions to be put regretting the above decision, gave as his reason that "this is a meeting called at short notice for the expression of views. Any formal resolution should have been circulated with the notice." In this very feeble way he side-tracked the wish of the meeting for a vote. The reason for this manoeuvre was obvious, for he had also rather weakly complained: "Is there no contrary view?" Well, Sir, there is no doubt that if a resolution had been put it would have been passed by an overwhelming majority against the Council's recommendation.

Later, under pressure, the President promised to send a notice to the Press stating that "it was generally agreed that the College should act in conformity with the general feelings of the profession in regard to the question of negotiations. . . ." No mention of this was made in the extract from the reputable daily paper that I quote above. The President added that the Council had told the Negotiating Committee what the College recommended concerning negotiation. What a travesty of the facts! The Fellows, who elect the Council, have never been given an opportunity to vote on this vital matter for obvious reasons.

However, our general practitioner colleagues can take heart, for at a very large meeting of consultants held in Birmingham on Nov. 27, where we were allowed to vote, only five voted for negotiating.—I am, etc.,

Leominster.

GEOFFREY HOUSDEN.

The Plebiscite

SIR,—I have just read Dr. H. B. O. Cardew's letter (Dec. 7, p. 873), and would hasten to question several points. Dr. Cardew states that the Government have " . . . a clear mandate from the electorate to pass the National Health Service Act." This is only a half-truth. (Remember Nazi propaganda—based on a half-truth but filled out and exaggerated with untruth?) The electorate did not give any "clear mandate" on the actual terms of the Health Act; it was not drawn up at the time of the election.

Now I should like to ask Dr. Cardew some further questions. Did the electorate also give a clear mandate for the control of foreign radio transmissions reaching this country? This has been announced and will shortly be put into effect, allowing us to hear only what the Government wishes us to hear. Did the electorate expect the Government to waste sixty-three million pounds of public money in supplying temporary aluminium huts when permanent houses were promised? Did the electorate expect the Government to immediately award themselves a greatly increased salary as soon as they were in power? Did the electorate expect the Government to re-establish postal censorship on outgoing letters from this country—a thing that has just been announced? Did the electorate ever intend the enormous increase of indirect taxation which is announced to meet the cost of this "free" Health Service? I presume that Dr. Cardew will answer, "Certainly they did." Any thinking man will then be able to value Dr. Cardew's opinion for what it is worth.

The great trouble is that the great majority of the electorate are totally incapable of giving any intelligent mandate to anybody on their own account. They are the 80% of the population who, sheep-like, will follow whichever 10% of the population makes the greatest noise—follow without giving any real thought to the implications underlying that thought.

My answer to the plebiscite is definitely "No," and I trust that the profession will show itself to believe still in the essential principles of the freedom of all men.—I am, etc.,

Tarbert.

A. KENNETH YOUNG.

SIR.—Letters in your columns from the "Yes"-men make interesting reading. The thanks of the whole profession are due to the Willesden Council, who have done more to effect unity in our ranks by disclosing at the psychological moment the intentions of the political party which, greatly to its own surprise, finds itself in office towards the doctors. If, as Dr. G. A. van Someren has stated (Dec. 7, p. 873), we say that we "decline to accept service under the Government scheme," that is the end of the scheme. It is as simple as that. What is the use of saying that we are prepared to negotiate still further, when Mr. Bevan himself said that he would decline to negotiate?

Dr. H. B. O. Cardew (p. 873) is anxious that doctors should not indulge in what he terms "political diatribes," although the whole National Health Act is a purely political matter which has been and still is untruthfully claimed to be a "free medical service." The 1944 "plebiscite" was such a confusing document that a very big proportion of those who voted could not be certain whether they were voting for or against the Act. Moreover, there are many of us who think that even the B.M.A. Council and the "Negotiating" Committee are at long last beginning to see the red light, and that the result of the 1944 vote does not represent the opinion of the profession as a whole. Even at that late period it was astounding to find how badly informed on the vital issues many doctors were.

The letter of Dr. Lennox Johnston (p. 874), socialist propaganda though it attempts to be, might have been useful in the days before the profession was alive to its danger. To-day it cuts no ice. I and many others are content to be "doctors even before we are citizens," for I can think of no higher degree of civic virtue than that practised by the doctor who honestly does his job. Moreover, I deny that the Socialist Government was "freely elected to power." Nobody was more surprised at their victory than the Socialists themselves, who owed their success very largely to the men and their wives who clamoured for early demobilization, and not because they had been promised a "free medical service"—a promise which was beyond their power to implement. In any case it is dishonest to call it "free."

For almost the first time in its history there is at last some semblance of solidarity in the ranks of the profession, thanks to Mr. Bevan and the "closed shop." Let us at all costs remain united and avoid obscuring the issue in a fog of words.—I am, etc.,

Brookwood.

H. M. STANLEY TURNER.

The Warning of Willesden

SIR.—I have been back in England just over a year after serving during the whole of the recent war, which, I understood, was to save the world from tyranny in whatever form and wherever it was found and to ensure that all persons should be able to live in peace and freedom—freedom of thought, speech, and action. The National Health Service Act has good as well as bad features. One result of its adoption by the profession is, in my opinion, alone enough to call upon every medical man and woman who values our heritage of freedom to refuse to co-operate in working the measure in its present form. This result would be the complete surrender of all independence in professional matters with consequent enslavement by the Minister of Health. Recent events at Willesden should be a warning.

This curtailment of personal liberty and freedom is appearing in many industries and professions in this country. In the name of all those things for which most of us fought—and for which many of our compatriots gave their all, their very lives—let the medical profession be the first to make a definite and united stand against this bid of bureaucracy further to extend its slimy, inefficient, clumsy, and cruel tentacles.—I am, etc.,

London, S.W.7.

R. F. GUYMER.

The B.M.A. and Public Relations

SIR.—Whatever the result of the plebiscite may be there is, I hope, no doubt that a fight is in store. To win this fight we must have the support of the lay public, and to gain that we need a radical change in our Public Relations Department.

Example being better than precept, the following will make the point clear.

We consistently refer to a "Health Act" when it is merely a "Treatment Act"—and an extravagant one. We have allowed control of certification without emphasizing that a certificate is "an expression of opinion" which we are prepared to substantiate in a court of Common Law (and to our peers). Even a Glasgow docker will pause if it is rammed home that his own doctor's opinion about his case is to be controlled from London.

A most able reply to our vilification about milk appeared in the *Journal* and a perfectly fatuous bleat about "proof in the Press, instead of vice versa."

No real attention has been drawn to our having appeal to the Courts. Some reference to *Magna Carta* needed, and even to Habeas Corpus, for we shall be from earning our living as effectually as if imprisoned.

No real emphasis has been placed on the hard fact of fighting our own battle we are fighting for the freedom of every individual in the land. A good title would be "Doctor Battle of Britain."

Finally we must prove that we are not obstructionists—improvement and progress, but are averse to mere mass movement and change for the sake of change.

I hope most sincerely that the B.M.A. will remember what every G.P. knows: that to get a layman to understand you must talk to him in his own language, and as we have to convert the working-class millions a spot of tub-thumping should not be beneath our dignity if in so doing we preserve English freedom.—I am, etc.,

Cromer.

A. HENRY GREGSON.

The Association and the Journal

SIR.—A correspondent suggests (Dec. 7, p. 873) that some doctors only join the British Medical Association because this is the cheapest and most convenient way of securing the *British Medical Journal*. I should have thought that there must be many others who do not join the British Medical Association because part of the subscription is for a journal which they do not want.

In any case would it not be advisable, both to take away from the Labour Government any excuse for suggesting that some members of the British Medical Association only join to obtain the *British Medical Journal* and to satisfy those who do not become members because they do not wish to contribute to the *British Medical Journal*, to institute, as well as the inclusive subscription for membership of the British Medical Association and for the *British Medical Journal*, separate subscriptions for each for those who do not wish both?—I am, etc.,

Allyth.

JOHN SLEIGH.

Remuneration under the Act

SIR.—I have read much in your correspondence columns concerning the freedom of the profession, etc., under the national health scheme, but little about the patient and the financial aspect. Many patients are going to lose an important right—the right to pay the doctor of their choice.

Concerning the financial aspect, we have recently seen almost 100% of the panel practitioners rising in righteous wrath over the 2s. increase and demanding the application of the Spens Report or their resignation would follow. With some alacrity the Minister agreed to this demand, but so that such unanimity cannot easily occur again he will leave the form and amount of remuneration under the scheme extremely vague. If he intended to pay us all £5,000 a year I am sure the number of voices raised against the scheme would indeed be crying in a vast wilderness.—I am, etc.,

Worborough Dale.

DENIS W. MAYMAN.

National Health Service Act

SIR,—Whereas most of us formerly favoured a national medical service, many of us now reject the scheme which has been offered in its place. The Act is a political instrument, and the Minister's insistence on appropriating the goodwill value of practices indicates his desire for absolute power over the profession and thus over the citizens whom they serve.

Secondly, according to a recent issue of the *Journal*, the Minister rejected a suggestion that a learned judge should have power to reinstate a dismissed member of the proposed Service, justifying this by an analogy which ought not to deceive a child by its logic. So he rejects criticism and learned guidance. The really competent do not surround themselves with a screen of unassailable authority. Thirdly, the prime cause of medical progress is research (I call to mind radium, radiography, sulphonamides, penicillin), which calls for hard unspectacular exertions, and instead of back-room research we are offered the brilliant footlights of mere reorganization.

I am not impressed by the benefits which it is claimed would accrue from the proposed scheme, such as security for young doctors who never asked for it, an equal deal for all classes, abolition of alleged exploitation, rotas, holidays, closer collaboration of doctors, etc. These benefits have been strewn riotously all up the garden path to obscure the fundamental philosophy of the Act, which is, for better or for worse, the annihilation of the doctor's independence.—I am, etc.,

Leeds.

LIONEL SUMMERFIELD.

SIR,—So much has been written in your columns concerning the National Health Service and the plebiscite that one would have thought the profession must be familiar now with most aspects of these matters. Nevertheless, it appears to me to be necessary to answer three of the letters in last week's *British Medical Journal*.

Dr. H. B. O. Cardew (Dec. 7, p. 873).—It is a favourite saying, but quite incorrect, that there is a clear mandate from the electorate to pass this particular National Health Service Act. There is a mandate for a National Health Service, and with that everybody agrees. The details of the present Act were not published to the electorate before the general election. In order to produce an efficient service it is not necessary to hedge the doctors about with a hundred and one distasteful conditions.

Dr. Lennox Johnston (p. 874).—There is no moral obligation as citizens to co-operate in putting into effect Acts passed without taking into account the views of those most closely concerned. The suggestion that the profession should take its "medicine" in a sporting spirit reminds one of the first whiff of the anaesthetic—"Now, now, this isn't going to hurt a bit."

Dr. B. Halley Stewart (p. 874).—The Act is law, and the Minister himself has no power to alter it or negotiate about anything that is specifically contained in the Act. Your correspondent assumes that the deputation would tell the Minister in unmistakable terms what it thinks of the Act. The Minister can have only one reply—to show them the door.

I should like to add that I consider myself as without undue bias and sympathize with some of the aims of the present Government. Nevertheless the actual methods whereby they are putting these aims into practice has placed a severe strain on one's good will.—I am, etc.,

London, E.14.

M. GODFREY.

The Act and Ophthalmic Treatment

SIR,—Ophthalmologists have good reason to feel disturbed by the letter from Dr. Leslie Hartley concerning the Act and ophthalmic treatment (Dec. 7, p. 873). There is a real danger inherent in unbalanced planning as exemplified in the constitution of key hospitals. No case has been made out that the patient is to benefit, and scant tribute is paid to the many ophthalmic surgeons who have been performing really good work at the periphery.

Planners—and medical planners are no exception—are notorious in their portrayal of the perfect State which will evolve as the result of their efforts, but we should not let this

blind us to the danger implicit in an ever-swelling bureaucracy and a concentration of authority in the privileged hierarchy.—I am, etc.,

Windsor.

CHARLES TAIT.

The Hogben Test

SIR,—I willingly take the opportunity of conceding that my letter (Oct. 12, p. 554) was in error in one detail, in that Shapiro did not come to work with me in London until after Dr. Zwarenstein's 1933 visit. I do so the more willingly because he was assisting Dr. Zwarenstein as a not yet qualified medical student during the period to which the preceding paragraph of my letter referred, and may therefore have been less conversant than his senior with other relevant facts correctly stated therein.

In so far as my letter involved any reference to himself or to his laboratory, I submitted it to Prof. Crew for his approval. For a reason stated below, the fact that Dr. Zwarenstein does not now recall the several conversations in which I acquainted him with pregnancy urine tests carried out in my own laboratory by Bellerby has little bearing on the issue raised in my letter. In any case Dr. Zwarenstein was in and out of my laboratory for some months while the tests were still in progress and could scarcely fail to be aware of what was going on.

I do not think that the alleged independence of the work Zwarenstein continued at my instigation and with my encouragement after I left South Africa is an issue which would have occasioned dispute if the South African Press had not boosted the use of *Xenopus* for pregnancy diagnosis as an indigenous South African discovery. This was why a former Capetown colleague, prompted by its local publicity and a forgivable zeal for the credit of South African science, brought it before the attention of readers of this *Journal* (1939, 1, 1258). That he then had the last word was the outcome of a personal letter in which he admitted intervening without full knowledge of the facts and expressed the hope that I should be satisfied with a face-saving gesture on his part. I did not care to embarrass a friend by protracting the controversy to comment on one remark which is of special relevance to the dispute. Since circumstances have changed, I can now do so.

My discovery of ovulation induced by anterior lobe extract with gonadotrophic activity was an unforeseen by-product of work on chromatic behaviour suggesting the possible identity of the w-substance of Hogben and Slome with the gonadotrophic hormone, hence also its equivalence to the gonadotrophic autacoid in the urine of pregnant women. If this view were correct the latter would evoke both ovulation and the white background reaction, either of which would then serve as an indication of its presence in urine. If it were (as it is) incorrect the gonadotrophic component of urine from pregnant subjects should evoke ovulation without evoking the white background reaction.

Prof. Gunn's final pronouncement (*British Medical Journal*, 1939, 2, 580), after correcting statements made in all good faith in his earlier one, includes the following:

"Prof. Hogben refers to pregnancy tests which, on leaving Capetown, he had entrusted to Drs. Ariel Goldberg and David Slome. I am informed by Dr. Goldberg and by Dr. Zwarenstein, who actively assisted in these experiments [*italics inserted*], that numerous tests were carried out during January and February, 1931, in the physiology department. The observations were made, however, not on ovulation in *Xenopus* but on colour changes in the skin."

That Prof. Gunn made in all good faith the last remark here printed in *italics* [*inserted*] is beyond question, since he freely admitted that he had no first-hand knowledge of the circumstances attendant on the discovery that *Xenopus* ovulates overtly in response to the gonadotrophic hormone. Seemingly neither Dr. Goldberg nor Dr. Zwarenstein disclosed the fact that they never reported the results of such tests for my comment. If this was because their samples failed to evoke ovulation as well as to evoke the more delayed full w-response, the so-called captivity effect (i.e., defective care of the test animal) furnishes a sufficient explanation of their failure. Seemingly the outcome convinced Dr. Zwarenstein that *Xenopus* does not respond by ovulation to pregnancy urine. What is clear is: (a) that he did not resume experiments on the effect of the latter until he had disclosed his belief that *Xenopus* undergoes ovarian regression in captivity, and then by recourse to freshly caught

ids; (b) the publication of the belief stated—one that he is not explicitly withdrawn—necessarily delayed publication parallel tests in my London laboratory.—I am, etc.,

University of Birmingham.

LANCELOT HOGBEN.

SIR,—I deeply regret the tone of the letter from Drs. H. A. Spiro and H. Zwarenstein (Nov. 16, p. 752). Since 1930 I have been very closely associated with Prof. Hogben and leagues in work on *Xenopus laevis* and well recall Dr. Zwarenstein's sojourn in London when Dr. Bellerby and myself were engaged on the work concerning husbandry technique which was necessary before *Xenopus* could be reduced as a reliable test animal for general use.

It is beyond question that the test arose from Hogben's discovery in 1929 that *Xenopus* ovulates in response to pituitary extracts. Under Hogben's leadership a thorough exploration of the implications of this discovery took place between 1930 and 1939, when the general applicability and reliability of the test were fully established. Prof. Crew, himself entirely familiar with the whole of the research in this field, very properly termed it the Hogben test.—I am, etc.,

University of Aberdeen.

F. W. LANDGREBE.

* * This correspondence is now closed.—ED., B.M.J.

Milk Priorities

SIR,—The medical profession have been asked to co-operate in the fairer distribution of milk supplies. In my work at infant welfare centres I have been struck by the fact that proprietary milk foods are not on the milk ration and can be bought at chemist's or welfare centre on presentation of a baby's ration book. The mother of a baby entirely fed on such a food can, if she wishes, get one pint (568 ml.) of liquid milk daily from the baby's ration book and one pint on her own.

While it might be admitted that this mother needed an extra allowance to make up for the extra strain of pregnancy and lactation, it can hardly be necessary for her to have two pints, or indeed one pint, for longer than a month or so unless she is in some other condition which will qualify her for it separately. Under present arrangements a family may get two extra pints of milk daily where the baby is fed on a proprietary food. I have also known cases where a proprietary food has been bought ostensibly for the baby but actually used for making cakes—a thing which would not happen if the former were on the milk ration.

National Dried Milk, on the other hand, is supplied by the local office instead of liquid milk. I suggest that this arrangement be extended to all dried milks specially prepared for babies. It should not be difficult to issue cards in place of the present rationing slips, which could be used anywhere to obtain these foods. Such a scheme need not, of course, include foods which are added to liquid milk.—I am, etc.,

Birmingham.

ELEANOR M. SAWDON.

SIR,—Surely in this question of milk certificates Dr. J. G. McDowell (Nov. 30, p. 834) is flogging the wrong horse. We have got to face the unpleasant fact that there is not enough milk being produced (in spite of the remarkable efforts of dairy farmers in the face of negligible imports of cattle food, which, I believe, is linked with the world shortage of fats) to supply the increased demand of the population. Dr. McDowell, as a preventive medicine specialist, can judge better than most of whether or not it is wise to stint the general population for the benefit of invalids.

Incidentally, did the Minister of Food slander the medical practitioner? From what I remember of the report of his speech he merely made a statement of fact—that the milk going to priority consumers had risen about 50% in 18 months, and in view of the shortage of milk he asked doctors to review their milk certificates and place a stricter criterion on the necessity for extra milk. And, Heaven knows, it is easy enough to give certificates under II (a) or (c) for the majority of one's patients without putting too great a strain on—I was going to say one's conscience—but perhaps one's interpretation of the regulations would be better.—I am, etc.,

Langport.

M. J. INGRAM.

Milk and Medicine

SIR,—Any doctor with a busy practice who has an inclination towards the State control of medicine should ponder over the recent dictatorial action of the Food Minister in cancelling all milk permits on Nov. 30. The result has been that for the last week I, like most G.P.s, have been inundated with applications for renewal of milk certificates, with all the consequent waste of time this entails.

Medicine is rapidly deteriorating into form filling—a grim warning of things to come unless we decide to unite and fight against control from doctrinaire politicians.—I am, etc.,

Croydon.

GLYN JAMES

Dicoumarol for Coronary Thrombosis

SIR,—In "Any Questions?" (Dec. 7, p. 882) there is a note on dicoumarol for coronary thrombosis. The advice given is "... 300 mg. dicoumarol are administered orally in one dose. This dose is repeated daily until the prothrombin time is 30 seconds. Doses of 100 or 200 mg. are given daily when the prothrombin time is between 30 and 35 seconds; above this level the dosage should be discontinued owing to the risk of haemorrhage."

The prothrombin time after a dose of 300 mg. dicoumarol does not begin to alter for 48 to 72 hours; it is possible to seriously overdose a patient by giving 300 mg. daily until the prothrombin time increases to 30 seconds. A much safer procedure would be to give 300 mg. daily for two days then stop altogether; it will be found that the prothrombin time will begin to rise about two days after the second dose and will continue to rise for three or four days, then will gradually decline, the base-line of prothrombin time being reached in approximately ten days after the first 300 mg. dose. When, by daily prothrombin time estimations, which are essential, it is found that the maximum time has been reached and the "days are shortening," a further small dose of dicoumarol may be given. Often 50 mg. is enough to increase the prothrombin time to the maximum after 24 hours; the patient at this stage reacts much more quickly. Still being guided by a daily prothrombin time estimation, further single doses of 50 mg. or 100 mg. may be given at irregular intervals; at this stage a daily dose is seldom necessary.

If for some reason the course of dicoumarol is stopped for some weeks or months, and then it is desired to resume it again, dosage must be very cautious. The patient may react rather violently and with unusual rapidity to doses as small as 50 mg.—probably 25 mg. is safer. It is true that little has been written on this subject in England, but the drug is being used and is very effective and only dangerous when the rather marked time lag between dose and effect is neglected or prothrombin times are not used as a guide. It is necessary to standardize the technique for prothrombin estimations and not to vary the method as results are all relative.—I am, etc.,

Epping.

FRANK MARSH.

Colonial Medical Service

SIR,—In my early years in West Africa I encouraged qualified friends, who had thoughts of going abroad, to join this Service, of which I am still a member. Recently I have been a less active propagandist. This month a report by a Commission on the Civil Services in West Africa has been published. If its recommendations regarding salary and service conditions for medical officers are accepted, and if the implications of these conditions are made known to intending recruits, I doubt if any sensible young medicals will sign on the dotted line.

Before the 1935 reorganization of service conditions administrative and most technical officers began at £400 or £450 per annum, and rose to either £920 or £960 per annum plus a non-pensionable seniority allowance of £72. The medical officer began at £660, reached £960 plus £72 in ten years, and, after a three years' halt, went on to receive £1,150 plus £100 at seventeen years. In 1935 the maximum of all these salary scales was consolidated at £1,000. The medical officer, apart from dropping £250 on his maximum, was now to do three years' probation without an increment and to take thirteen years to reach £1,000. From his third year onwards his salary

was £132 less than that of his predecessors in the corresponding year of their service. Further, private practice, formerly a right, now became a privilege, and pensions were very much reduced. Officers then in the Service fought these new conditions and managed to force the Colonial Office to raise the medical officer's maximum to £1,200. With the addition of private practice, which, with luck, can average many hundreds a year, this was fairly reasonable at the time. The value of private practice can be gauged from the fact that Governments, never generous, offered to health officers and others an allowance that averaged over £130 per annum in lieu of such practice. Health officers accepted this allowance, although it was much less than the average private practice, because their opportunities for promotion to executive posts, with considerably higher salaries and pensions, were much better.

Since 1940 the cost of living has risen enormously in West Africa, even more than in Britain. No relief was given to European staff until 1944, when quite inadequate allowances were given to junior officers only. On the other hand junior African staff was granted higher salary scales, and all African staff was given a cost-of-living allowance which in some cases is as high as 75%.

Early this year the Commission was appointed to report on salaries, etc. In the opening paragraphs of its report the Commission remarks that many of the officers giving evidence were suffering from strain and ill-health directly due to war conditions, and that many were very pressed for money. Later paragraphs refer to the effect on salaries of supply and demand, of wage levels and conditions of employment in Britain, of the responsibilities attached to different posts, and, with special reference to doctors, of the shortage of professional men in the Empire. The report then goes on to recommend increases for all grades, African and European, with the solitary exception of new European medical officers who join after the recommendations take effect.

For administrative and other officers initial salaries are to be raised to £510, and the maximum to £1,200. Medical officers at present in the Service, whose salaries range from £660 to £1,200, are to have from £880 to £1,400. But a medical officer who joins next year will begin, according to his postgraduate experience, at a salary of between £680 and £860; his maximum is to be £1,200, the same as at present. The £880-£1,400 scale is obviously in the nature of a bribe to keep the present incumbents reasonably happy. It seems fair to assume that the members of the Commission thought that the laws of supply and demand, U.K. wage levels, and professional responsibilities must not operate in the case of medical men; yet they must have known of the existing recruiting difficulties. It should be noted that the medical officer's maximum of £1,200 per annum is composed of £900 "basic" pay plus £300 "expatriation" pay—an indication that the Commission considers the income of the medical man in Britain, at age 36 to 40, to be £900 per annum.

Another recommendation is that private practice be abolished. Members of the Service suggested this themselves, and most will accept it, *provided* adequate compensation is granted. The Commission suggests £100 per annum additional pensionable emolument. This will appeal neither to the man who has habitually made five to ten times that amount nor to the health officer who is no longer to have the monopoly of high executive posts.

So far I have considered medical officers' salaries. The senior medical officer, who now usually has lucrative private practice, is to jump from £1,400 per annum to £1,435; all other departmental officers now on £1,400 will quietly proceed to £1,600. The senior medical officer may get £100 in lieu of his private work; on the other hand he may be regarded as an executive officer and have no such compensation. We will then have the anomaly of a medical officer on £1,400 plus £100 being asked to accept promotion to £1,435 only. A similar anomaly existed for years on the health side; medical officers of health on a total income of £1,350 had to accept £1,200 on promotion.

These recommendations, together with the 1935 attempt to reduce medical officers' salaries, reflect Colonial Office policy, which seems to be that professional and technical men in the Colonies must not receive higher salaries than administrative officers. It is recognized that the latter have, in Britain, much poorer prospects than medical or veterinary men, possibly even

poorer than agriculture and forestry graduates. The Commission's recommendation for large salary increases for junior African staff and for greatly increased African pensions will result in inflation and high taxation, which will nullify the £150-£200 per annum increases given to most Europeans. How much more will they affect the medical officer who is to have no real increase?

I think, Sir, that it should be made known to prospective recruits that these proposals, if implemented, will give them no higher income than under present conditions and will almost certainly lower their standards of living. Should the recommendations be accepted, I have no doubt that you will be asked by members of the B.M.A. in West Africa to refuse to publish the Colonial Office advertisements in so far as they refer to West Africa.—I am, etc.,

WEST AFRICA.

Medical Future of the Colonies

SIR,—With reference to the letter by "Still Another West Coaster" (July 13, p. 64), I would like to emphasize a few points. The excessive amount of office work entails handing over a large proportion of patients to a dispenser whose diagnoses are not worth the paper written on; returns of diseases are thus rendered almost valueless. The public do not pay a medical officer in the neighbourhood of £1,000 per annum to waste time doing office work within the compass of an intelligent child of twelve. Government should entrust such work almost entirely to African subordinates and make them pay the penalties of any dereliction of duty. To save a few pounds Government are prepared to sacrifice an incalculable sum in medical efficiency. The loss of clinical education thus caused must react on a medical officer, and after a dozen years or so, when he should be a very competent tropical practitioner, he is fortunate if he is no worse than when he first arrived in the country. This loss of clinical knowledge is bad enough for the medical officer, but who can gauge the possible loss to humanity?

The health department is grossly understaffed, so that a large proportion of its work descends on the already well-loaded back of the medical officer. Sanitation is of immense importance, but medical officers still have their thousands of sick and maimed who are not prepared to wait for a sanitary millennium. It seems to be ingrained in the minds of administrators that volume of correspondence and efficiency go hand in hand. But the hall-mark of efficiency is to ensure that a minimum of hindrance is offered to the practical side. Administrators have their difficulties, not the least of which is lack of funds. But Governments must be plainly told that if they want an efficient medical service, then they must pay for it. Medical administrators, practically always drawn from the health department, are not enough in contact with a medical officer's work to appreciate his difficulties. It would be better if they consulted with him more and became better acquainted with the practical side of medicine. Medical officers, in addition, have no means of collective consultation: we seldom see each other.

I wish to emphasize that I am not a disgruntled officer and am fully satisfied with my treatment both by Government and my department, and these few candid criticisms are offered solely in the hope that they may contribute to the advancement of the Service.—I am, etc.,

"WEST COAST M.O."

Anaesthetic Inhibition of Transfusion Reaction

SIR,—On reading the letter from Dr. P. H. Moore (Sept. 7, p. 340) I recalled a case which came to my notice several years ago which seems to bear out the idea that anaesthesia will often control severe reactions, allergic or otherwise. The case was that of a young man suffering from a severe septicaemia who was given several blood transfusions. After one of them he developed a reaction which threatened to be fatal. Cyclopropane was administered, and his condition returned to what it had been before the transfusion. Immediately after discontinuing the anaesthetic the reaction returned in all its former severity, and the procedure had to be repeated several times before the danger was over.—I am, etc.,

Montreal.

I. J. PATTON.

Generalized Vaccinia

SIR.—In view of the rarity of the above condition it occurred to me that a brief account of a typical case might be of value. A girl aged 13 was unsuccessfully vaccinated in infancy. As a preliminary to entering the nursing profession she was required to be vaccinated or revaccinated. This operation was duly performed on Nov. 16 with a single insertion of fresh lymph.

On Nov. 20 the dry dressing was changed, and at that time there was a typical clean vesicle of about 1/2 in. (1.25 cm.) in diameter without any surrounding inflammation whatever. Two days later the girl complained of vague abdominal pains, and he was treated with aperients; but the arm commenced to pain, and ached continuously. By Nov. 24 temperature started to rise, and an axillary gland became enlarged. The temperature was 100.6° F. (38.1° C.) and the patient felt definitely ill. Aspirin 10 gr. (0.65 g.) given at night caused a rapid fall of temperature accompanied by profuse sweating and prostration in the small hours of the next morning. On Nov. 25 the temperature rose again to 102° F. (38.9° C.); this day papules were observed on the back and shoulders, one small one on the abdomen. From a crop of 6 or 8 the number increased on the following days until there were 30 or 40. Many of these papules became vesicles and a few pustules, but all with an indefinite abortive appearance.

Having seen many cases of chicken-pox and smallpox I can state with some confidence that these spots were like neither those of chicken-pox nor of smallpox; this because each papule did not change into a true vesicle nor vesicle to pustule, but aborted in an indeterminable condition—i.e., papulo-vesicle and vesicle-pustule. There was one papule at the back of the ear and another on the forehead.

Meanwhile the vaccination remained perfectly clean and uninfected, though the vesicle enlarged to 1 in. (2.5 cm.) in diameter. On the night of Nov. 25–26 the temperature, which by the latter day was 103.6° F. (39.8° C.), was again brought down, with sweating and prostration. But on the 27th the temperature fell to 99° F. (37.2° C.) and was normal next day. The axillary gland subsided and spots commenced to disappear.

On Nov. 26, when the temperature was at its highest point, the patient complained of a headache which caused me some perturbation in view of certain sequelae of vaccination of many years ago. But reflexes were normal, though the headache was severe enough to cause photophobia. The girl was languid and listless, and remained so until Nov. 27, when her whole appearance changed from dullness and lethargy to alertness and normality. She was allowed up on the 30th, but is still without appetite and looks very pulled down, as if she had had a long illness.—I am, etc.,

Guilford.

J. A. BELAM.

The Cough Syrup

SIR.—Dr. Eldon M. Boyd's paper on "The Cough Syrup" (Nov. 16, p. 735) raises once again the question of the effectiveness of "expectorant" drugs commonly prescribed by the medical practitioner. Disregarding for the moment the subject of the value of faucial demulcents in chronic bronchitis, I should like to draw attention to Dr. Boyd's statement "... expectorant drugs added to the syrup ... increase the output of respiratory tract fluid. ..." It is important to realize that the author's evidence for this assertion is based upon experiments performed on "lightly anaesthetized or decerebrate animals." Dr. Boyd has published a series of papers on this subject in recent years, but to examine the warrant for his conclusions, which are so important to the practising doctor, it will perhaps suffice to quote only one of his publications.

Perry and Boyd (1941) demonstrated an increase in the respiratory tract fluid of animals when the doses of the expectorant drugs were as follows: powdered ipecacuanha *B.P.* 1 g. per kg. of body weight; thymol 1 g. per kg. of body weight; ammonium carbonate 0.5 g. per kg. of body weight. It will be seen therefore that a rabbit weighing 2.5 kg. received about 40 gr. of powdered ipecacuanha or 20 gr. of ammonium carbonate. Such quantities would cause immediate vomiting if they were administered to a normal man. Furthermore, if allowance is made for the small size of the

stomach in the rabbit and cat compared with the stomach of a man, it is obvious that an extraordinarily high concentration of the drugs must have been produced in the fasting region of these animals. Rodents, including the rabbit, are of this peculiar in that they cannot vomit even when fully conscious. It would, however, be interesting to witness the behaviour of a normal cat (neither lightly anaesthetized nor decerebrate) on receiving 40 gr. (2.5 g.) of powdered ipecacuanha on an empty stomach. Adopting the author's weight basis of dosage, it is also instructive to note that for a man weighing 70 kg. the corresponding amount would be about 1,200 gr. (75 g.), or six hundred times the official maximum expectorant dose. Dr. Boyd himself, in his recent paper, points out that the dose of syrup of squill *B.P.* which failed to produce an increase in respiratory tract fluid was equivalent to a draught of one quart (1,140 ml.) for a man of average weight.

Now, Sir, it is not denied that ipecacuanha, ammonium chloride, ammonium carbonate, and other "reflex expectorants" can affect the respiratory tract in man if they are given in emetic doses. A simple clinical demonstration is provided by giving a tablespoonful (14 ml.) of ipecacuanha wine to a child with non-diphtheritic croupy bronchitis. Not only does he vomit but he also coughs up a large amount of mucus, thereby effecting demonstrable changes in the physical signs in his lungs and obtaining a considerable measure of relief from his respiratory distress. It is remarkable that pharmacologists working on laboratory animals should have found it necessary to devise experiments to instruct us on this matter; and it is indeed ironical that the chief conclusion to be drawn from their painstaking work is that the animals selected are much less suitable for the purpose than man himself.

A few years ago I published (1939, 1940, 1941) a series of papers on the action of potassium iodide and the common "reflex expectorants" on the output of sputum in patients suffering from chronic bronchitis. No significant effect could be demonstrated from the administration of sub-emetic doses of ipecacuanha, ammonium chloride, ammonium carbonate, or the iodides. In the light of my observations on the validity of observations carried out on laboratory animals, it will be surmised that I am bound to accept any conclusions from such work with the greatest reserve. Nevertheless, it is noteworthy that Perry and Boyd (1941) record an attempt to make their dosages comparable with those with which we are familiar in clinical practice and state: "Using a dose of ammonium chloride corresponding on a body-weight basis to that of Alstead, we also could detect no increased output of respiratory tract fluid."

I am not in a position to state categorically that sub-emetic doses of "reflex expectorants" have no action whatever in chronic bronchitis, but I am convinced that they do not increase the output of sputum. Those who make other claims for these drugs as commonly prescribed may reasonably be asked to produce evidence for their opinions. Finally, it seems to me that an unfounded belief in the value of "expectorants" has had the unfortunate result of distracting attention from other and more valuable measures in the general management and drug therapy of this incurable disease.—I am, etc.,

Glasgow.

Air-borne Infection

SIR.—Your leading article on the control of air-borne infection (Nov. 30, p. 820) repeats the statement made a few days previously to the Royal Society of Medicine that it is more difficult to supply clean, safe air than to supply clean, safe milk or water. May I suggest, with great respect if rather bluntly, first, that the statement is not true. There is no building in the country that is not surrounded by an unlimited supply of safe, clean air which can be obtained by opening the window; but there is none at all where clean water or milk can be obtained so easily. Secondly, I would suggest that what the Section of Epidemiology really meant was that it is much more difficult to supply disinfected air than to supply disinfected water or milk.

If the most important problems of the age in hygiene cinema. The hygienic objection to the cinema is not the sn or even the rubbish that is so often shown on the screen, the poisonous stench in the auditorium in so many cases. Such foul air cannot conceivably be healthy, and it is as certain as anything can be that it spreads disease. It seems to me to be of no more than academic interest whether the disease is spread in this instance by bacteria or viruses, or by whatever it may be that makes the air stink. The difficulties of disinfecting the air in cinemas are obviously overwhelming, and even if it could be done there would still be the difficulty of removing the poisons and the smell. It would be very much easier to remove the foul air and replace it from the unlimited supply of safe, clean air outside. Air-conditioning schemes all break down because the designers will persist in trying to do too much; they try to improve on the perfectly safe, clean fresh air outside the building. All that is required is fresh air and reasonable warmth.—I am, etc.,

Wetherby.

Juvenile Delinquency

SIR,—On Nov. 16 at the Inter-Clinic Conference held in London papers were read by Miss Hamilton and Miss Clare Britton which summarized their experiences in the management of hostels for difficult children, and the suggestions which they made were both provocative and of extreme value. The concern which is generally felt throughout the country over the present rate of delinquency, particularly among the young, and the measures about to be debated in the House on this matter make it, I feel, essential that due regard shall be paid to the full implications of any "institutional treatment" which may be considered.

To some of us who are intimately concerned with the investigation of delinquency it is already apparent that gross personality deviation is not infrequently accompanied by cerebral cortical disturbance of varying degree. In a paper read before the Electro-encephalographic Society I indicated that of a group of 63 cases referred for examination from courts of summary jurisdiction 36.5% on complete investigation might properly be considered to suffer from epilepsy, or "epileptic equivalents." During the discussion which followed this paper other members of the meeting were apparently even more prepared than I to accept this view. In another paper read before the Royal Medico-Psychological Association I quoted Prof. D. K. Henderson when he asked in the case of psychopathic personalities for "an indeterminate sentence, discharge depending not upon the expiration of time but upon the proper establishment of adequate social patterns."

Since it may come about that the value of treatment in a controlled environment for the delinquent child and the persistent offender may be recognized, may I perhaps emphasize that the composition of the "controlled environment" will be of the very greatest importance. In no single respect will this be more so than in the selection of the permanent resident staff—i.e., masters, matrons, etc. However we may look at it, the environment is of itself of considerable therapeutic importance. To those who may be charged with the duty of providing such institutions this single factor may well prove to be a major difficulty. May we hope, Sir, that the experience which some of us have gained during these latter years may be available and utilized by administrators, and in particular that the experience of workers such as Miss Hamilton and Miss Britton may not be overlooked.—I am, etc.,

Taunton.

R. SESSIONS HODGE.

"Benadryl" and Exudative Pulmonary Tuberculosis

SIR,—As I have no opportunity (being in the Service) of dealing with cases of tuberculosis, I should like to put forward a suggestion to be tried by others who are dealing with the problem of the chemotherapy of pulmonary tuberculosis.

In view of the known activity of "benadryl" (β -dimethylaminoethyl benzhydryl ether hydrochloride) in blocking various types of antigen-antibody reactions, I think it would be of interest to know what effect, if any, "benadryl" has on an early exudative pulmonary focus. If there was a response to this "anti-allergic" agent, in that it removed the reactive oedema of the pulmonary lesion, then perhaps it is reason-

able to assume that the vascular supply and drainage of the affected area would be improved, and the access of chemotherapeutic remedies to the lesion facilitated, with removal of various catabolic substances. This effect could be followed by repeated x-ray examinations. I would assume too, that the drug could be administered in order to be able to assess correctly the real extent of the damaged pulmonary tissue after all the surrounding oedema had been removed.

I do not wish to suggest, of course, that "benadryl" has any influence whatsoever upon the course or treatment of pulmonary tuberculosis, but only that it may have some possible use as an adjunct in its investigation and treatment. The idea outlined should not be lightheartedly dismissed, since there may be an element of value in it; and, accordingly, should at least be put to trial before becoming just one more addition to the vast heap of antiquated empirical remedies for tuberculosis.—I am, etc.,

LEON RADCLIFFE,
Lieut., R.A.M.C.

Antimalarial Drugs

SIR,—I have read with interest Dr. Ryan MacMahon's report (Nov. 30, p. 844) to Dr. Hamilton's letter. There are two important factors which must be taken into consideration when evaluating antimalarial drugs: (1) the strain of species and (2) the degree of immunity of the patient, whether natural or acquired.

It has been proved beyond all doubt that there are geographical strains within a species, and they vary in clinical virulence. For example, the amount of quinine required to control attacks of Rome and Sardinian strains of malignant tertian malaria was found to be eight times as much as was necessary to control attacks caused by two Indian strains, two from West Africa, one from Tanganyika, and two from Rumania. These studies were made on primary cases which had not previously suffered from malaria. The following table may be of interest.

	Total of Quinine, in gr. (and g.) during a Primary Attack	Total of Quinine, in gr. (and g.) during the Whole of the Course	Average per Case during Primary Attack, in gr. (and g.)	Average per Case during Whole Course, in gr. (and g.)
Indian and other strains. No. of cases treated: 19	772 (50.2)	2,233 (145.1)	40 (2.6)	117 (7.6)
Rome and Sardinian strains. No. of cases treated: 13	4,343 (282.4)	21,894 (1423.1)	335 (21.8)	1,650 (109.2)

This does not mean that there are no tropical strains which are as virulent as the Rome and Sardinian strains, but it does show that there are degrees of virulence and resistance to some antimalarial drugs within strains of the same species of plasmodia. Also the amount of antimalarial drugs necessary to cure a primary attack is much more than is necessary to cure relapses or reinfections by the same strain of parasite. This is especially so if the patient has had several days of fever in a primary attack before treatment is given. Successive relapses usually respond to smaller quantities of antimalarial drugs than does the primary attack—due, one imagines, to the increase of acquired immunity built up as the result of previous attacks. This may be the reason why some people believe that drugs, especially synthetic drugs such as mepacrine, vary in their efficacy.

Any who are interested may like to look up an article of this subject in the *Proceedings of the Royal Society of Medicine* (June, 1932), "A study of induced malignant tertian malaria," by James, Nicol, and Shute.—I am, etc.,

P. G. SHUTE,
Assistant Malarialogist,
Ministry of Health.

The Report of the Standing Committee on the Rehabilitation and Resettlement of Disabled Persons has recently been published (H.M. Stationery Office, price 4d.). Measures required to deal with cases of heart disease, tuberculosis, deafness, and psychoneurosis, and the facilities available for vocational training and industrial rehabilitation, are described. There is a classificatory table of disabled persons registered on Aug. 19, 1946.

Two advances in Opiate Medication

DILAUDID

TRADE MARK dihydromorphinone

Improved Morphine Preparation

Whilst the analgesic power of "Dilaudid" is five times as great as morphine its hypnotic effect is considerably weaker. The euphoria element is largely subdued and addiction risk correspondingly lowered. Tolerance is improved, an increase of dosage rarely necessary. The effect on peristalsis is slight and much less persistent than with morphine.

DICODID

TRADE MARK dihydrocodeinone

Powerful Antitussive

Occupying a place midway between morphine and codeine, "Dicodid" exerts a selective influence on the cough centre. Better tolerated than morphine, it also interferes very much less with expectoration. Causes no constipation.

The Dakin and West

Erythropoietic Fraction of Liver

The clinical efficacy of Anahæmin B.D.H. in pernicious anæmia is remarkable even in the presence of factors tending to limit its activity.

For example, in some cases in which iron is not freely and abundantly available, erythropoiesis induced by Anahæmin B.D.H. may temporarily outstrip hæmoglobinisation, producing a hypochromic anæmia. The provision of an adequate diet during treatment is usually sufficient, however, to provide all the necessary iron and other hæmatinic substances required to produce a balanced and prompt erythropoiesis in response to treatment with Anahæmin B.D.H. Further information is available on request.

Pharyngitis and Tonsillitis

effective therapy with ARGYROL

ARGYROL has proved its value for controlling infections of the nose and throat. Many eminent authorities have noted that the best results are obtained when ARGYROL is specified in all prescriptions.

There are sound chemical and physical reasons for this. The silver in ARGYROL is in a much finer state of colloidal dispersion, also there is a far greater degree of Brownian movement, which logically must result in greater therapeutic activity. This is not true of ordinary mild silver proteins, for ARGYROL is the only silver salt that does not tend to become irritating with increased concentrations. SPECIFY ARGYROL IN ALL PRESCRIPTIONS.

"SULPHANILAMIDE TULLE" CREAM

In order that the doctor may have a free choice of bacteriostatic dressings, SULPHANILAMIDE TULLE Cream (Optrex Brand) is now offered to the medical profession.

SULPHANILAMIDE TULLE Cream can be used as an ointment, or applied on a sterile spatula direct to a diseased or injured area, or spread on gauze, linen, or oiled silk.

The formula is the same as that used for the emulsion in Sulphanilamide Tulle which—available only on prescription—has had continued success during the past years due to its acceptance and appreciation by doctor's as a product based on the latest scientific knowledge.

SULPHANILAMIDE TULLE Cream is indicated in the treatment of burns and scalds as a primary dressing to prevent infection. It is also successful in the treatment of septic skin lesions of indolent ulcers, and for burns and scalds when infection has already occurred. The dressing when used in combination with SULPHANILAMIDE TULLE Cream need only be changed infrequently and healing proceeds rapidly without disturbance of new epithelial cells.

SULPHANILAMIDE TULLE Cream is sold in tubes and is thus maintained sterile and ready for use. The sterility and composition of each batch is controlled by bacteriological and chemical examination.

Composition—SULPHANILAMIDE TULLE Cream contains 10% w/w Sulphanilamide in Paraffin-Lanolin-Water emulsion.

Obituary

SIR WILLIAM J. COLLINS, K.C.V.O., M.D., F.R.C.S.

*Former Vice-Chancellor of London University,
Consulting Surgeon, Royal Eye Hospital*

We regret to announce the death of Sir William J. Collins on Dec. 12, at his home at Regent's Park. Some men fail to reach the goal expected of them because they lack one talent short of ten, but others just miss the glittering prizes because nature has been too prodigal in their endowment. Nowadays if Leonardo da Vinci returned he might find it advisable to be either a painter or an engineer, one or the other. Sir William Collins had such exceptional gifts that they might have carried him to a supreme position in almost anything he undertook—in law, medicine, politics, university administration, municipal government. He took his M.D. when he was only twenty-three, and his F.R.C.S. when he was twenty-five. He was a senator of his university within eight years of leaving it as a student. He was chairman of the London County Council before he was out of his thirties. The promise was so abundant, yet somehow the harvest, while plentiful in diverse achievement, did not quite fulfil the expectations of those who had watched the splendid ripening of his gifts.

When William Job Collins was a student at St. Bartholomew's in the 'eighties he was thought to be heading for great eminence in surgery, but actually he reached no higher than a moderate position in ophthalmology. When he entered Parliament after two unsuccessful attempts, one of them as candidate for his own University of London, having behind him already a noteworthy career in local government and in front of him the splendid reign of power of his (Liberal) party following the General Election of 1906, many people centred great hopes around the new Member for West St. Pancras. They saw in him a possible future Prime Minister—the first medical man to hold the supreme position in the Government of this country. But he never received even minor Government office and spent only five years in the House of Commons, and one year more at a later period when he was returned for Derby at the end of the war of 1914–18. He made no shining success in politics—perhaps he was too high-minded to be a successful politician. He once declared after his five years in Parliament that the medical profession was suspect in the House of Commons, where the prevailing feeling was that the profession was "out for fees."

There may have been something in his make-up—perhaps the Huguenot strain (he was a member of the Huguenot family of Garnault) which made lesser people feel inferior and therefore antagonistic. Or another explanation of the enigma of William Job Collins may be that his qualities were suited for the chair rather than for the Bench, even the Front Bench. He was a chairman sent from heaven. He had all the qualities a chairman ought to have—urbanity, firmness, grasp of detail, an eye to the main issue, the ability to come to the point and bring others there, and again and always urbanity. His first great experience of the chair was in the London County Council in 1897. A few years later he was chairman of the London Education Committee. He presided over the Sanitary Inspectors Association, over the Chadwick Trust, over the Central Council for District Nursing, over the Medico-Legal Society, over innumerable bodies having an educational and reforming purpose. He was always being made chairman of select committees, dealing with such subjects as agricultural wages, the minimum wage for miners, accidents to railway servants, and always he justified the choice. With Collins in the chair everybody was confident that the work would proceed to some useful conclusion. He had in him the making of a great diplomat. As Government plenipotentiary at three International Opium Conferences at The Hague in 1911–12, 1913, and 1914 he did extraordinarily good work, for which he received the special thanks of the British Government. It was on this subject of opium and the control of narcotic drugs generally that he served the *British Medical Journal* for many years as an occasional contributor. His writings, again, reveal how widely he spread himself. In addition to two books on ophthalmology

he wrote biographies of Spinoza, Sir Samuel Romilly, and Edwin Chadwick, thus exercising three of his great interests—philosophy, law reform, and sociology. He also wrote many essays on ethics and law, on alcohol and drug addiction, on physics and metaphysics, on evolution and specificity in disease, and when the war of 1914 broke out he produced a volume on the *Aetiology of the European Conflagration*.

Sir William Collins's professional work seems to take a minor place by the side of all this public service. He was surgeon and later consulting surgeon to the Royal Eye Hospital and the Western Ophthalmic Hospital, and ophthalmic surgeon to the Hampstead and North-Western Hospital. In 1918 he received the Doyné medal in ophthalmology. The various work for the profession and for the public with which at one time or another he was associated almost defies chronicle. For prolonged service his membership of the Royal Commission on Vaccination which sat from 1889 to 1896 and the Royal Commission on Vivisection which sat from 1906 to 1911 is outstanding. He was a member of the Council of the King's Hospital Fund. In this connexion one characteristic example of his individuality may be noted. In 1919 he refused to sign a report of that body stating that hospital officers should make arrangements for their own pensions by resorting to profit-earning insurance companies. Collins in a dissentient memorandum demanded more generous treatment of hospital officers by the bodies employing them, and earned thereby the warm gratitude of hospital staffs. For nearly thirty years he was honorary secretary of the League of Mercy; he was a member of the City Churches Commission and of the Treasury Committee on University Colleges. During the war of 1914–18 he was commissioner for the Red Cross in France. One distinction which he took to himself was that of having been a pioneer in the advocacy of motor ambulances, which he first proposed as early as 1902. London's fine ambulance service owes not a little to his early initiative. Another matter which interested him greatly was the reform of death certification, on which subject he led three deputations to three successive Lord Chancellors.

A man who was great in many respects, but greatest of all perhaps as a citizen, has passed away. A stimulating biography of William Job Collins might be written, and we hope it will be, if only to show that the gods can be too generous to mortals.

Dr. W. G. AITCHISON ROBERTSON, formerly of Edinburgh, and author of books on medical jurisprudence and toxicology and on public health, died at Bournemouth on Nov. 18. He had a distinguished career at Edinburgh University, where he graduated M.B., C.M. in 1887, M.D. with gold medal for his thesis in 1890, and D.Sc. in Public Health in 1892. He was elected a Fellow of the Royal College of Physicians of Edinburgh in 1891 and received the Parkin prize in 1901. In the early part of his career at Edinburgh he was resident physician at the Royal Maternity and Simpson Memorial Hospital, and physician to the Royal Public Dispensary. He was called to the Bar as a member of Lincoln's Inn and became lecturer in medical jurisprudence and public health in the School of Medicine of the Royal College of Surgeons of Edinburgh. Aitchison Robertson was examiner in medical jurisprudence for the Scottish triple qualification and in bacteriology and laboratory work for the Edinburgh D.P.H.; he also examined for the Universities of Glasgow and St. Andrews. His *Manual of Public Health* reached a fourth edition in 1921, and his *Manual of Medical Jurisprudence and Toxicology* a fifth edition in 1925; he also wrote *Aids to Public Health* (third edition, 1933), and *Aids to Forensic Medicine and Toxicology* (eleventh edition, 1938). Two other small books by him, *Medical Conduct and Practice* and *Student's Guide to Vaccination*, appeared in 1921 and 1922. The Royal Society of Edinburgh elected him a Fellow and his university gave him the degree of D.Litt.

Dr. ISABEL MARGARET MACGILLIVRAY was killed in a motor-accident in Germany on Nov. 19. A daughter of the late Charles Watson MacGillivray, M.D., F.R.C.S.Ed., she studied medicine at Edinburgh University and graduated M.B., Ch.B. with honours in 1924, taking the M.R.C.P.Ed. two years later. She had been resident medical officer to the Manchester Babies Hospital, house-physician to the Royal Hospital for Sick Children, Edinburgh, and assistant in the department of pathology of Edinburgh University, and also clinical assistant at the Vienna University Kinderklinik. At the time of her death she was engaged on statistical work for the Government on the subject of nutrition in Germany.

Medical Notes in Parliament

SCOTTISH HEALTH BILL

In the House of Commons on Dec. 10 Mr. JOSEPH WESTWOOD, Secretary of State for Scotland, moved the Second Reading of the National Health Service (Scotland) Bill. His opening remarks were recorded in last week's issue of the *Journal* (p. 925).

Mr. Westwood concluded by pointing out that the Boards of Management, whether of teaching or non-teaching hospitals, would in the first place retain the endowments of their particular hospital. The method of reviewing and adjusting the application of endowments followed the precedent of the Educational Endowments Act of 1928. By clause 76 they sought to delete from the Nurses (Scotland) Act of 1943 the provision which made it impossible for anyone starting on a course of training after Aug. 4, 1948, to qualify for admission to the Scottish Roll of Assistant Nurses.

Mr. J. S. C. REID said there was general agreement that the time had come for a great extension of health services in Scotland. The first principle of the Bill should have been to keep Government control to a minimum. But the Bill put far too much power into the hands of the Secretary of State for Scotland and left far too little scope for initiative and responsibility to those who were to run the services. There was also far too little scope for variety in organization; centralization was bound to lead to rigidity. He moved the rejection of the Bill.

Conciliation and Agitation

Mr. McLEAN WATSON said, so far as members on the Government side of the House were concerned, if public money had to be expended there must be public control. He agreed with Mr. Reid that there was too much of the Secretary of State in the Bill and too little of the local authorities. He thought that Mr. Westwood had gone too far to conciliate the professional classes—the doctors, dentists, pharmacists, and others. He had given them far more say than he ought to have done in the various committees which would have to work this scheme. An attempt might be made in the Committee Stage to secure less control by the Secretary of State and more control by the local authorities, the county councils, and the town councils, which up to now had been the local health authorities. He thought that the agitation which had been carried on by the doctors and others had induced Mr. Westwood to grant those professional classes representation on the various bodies to be set up in a larger proportion than was justified. The responsibility for saying whether a place was overstaffed or understaffed with doctors and for sending doctors where they would be most required rested with a chairman and five members of a medical practices committee. Three members of that committee were definitely to be doctors, but he failed to find in the Bill an indication of who the two others were to be.

He welcomed the general principle of the Bill, but said that when the House was considering the regions for hospital management Mr. Westwood should ensure more harmony among the various authorities which were brought in than had been secured under the Local Government Act of 1929, otherwise conflict would start between the county councils and the large burghs which would be brought into the regions for the control of the hospitals. It was of great importance to the people of Scotland that the measure should be brought into operation as soon as possible, although it would call for considerable increases in rates.

Training of Medical Students

Sir JOHN G. KERR said that the Bill, except in detail, was a replica of the English Bill. It was the product of diligent artificers working in the murky recesses of a Whitehall office. Some of the brightest stars in medical history had shone from the universities and voluntary hospitals of Scotland. These great leaders in medicine and surgery were the teachers of the doctors to come. The success of any Parliamentary enactment was tremendously influenced by the character of the men who had to carry its provisions into effect, and Scotland had at present the very finest material coming into the science of medicine.

What about training? The leaders of the profession at present gave that training in the voluntary hospitals because even in an honorary post they would have the opportunity to inspire the students and would be paid back indirectly by forming a clientele of practitioners who would come back to consult them later on. The type of man who went to a university and later into the profession was not the type of person who was interested in a salaried service where promotion went merely by seniority. He was a young man who had a good

idea of his own capacity and would only go into a profession in which he thought there was a fine future. Although he had spoken of the great voluntary hospitals the House must not forget that all over the country a large amount of modest research was done by the ordinary country practitioner. He perhaps with the aid of his cottage hospital, was doing work of the greatest importance. If the Bill was passed into law it would become one of the greatest disasters to the health of the people.

Miss HERBISON said that services under the Bill would be available to everyone without limitation and would prove of inestimable benefit. It had been found that dependants often refrained from calling in the doctor when his services were most necessary because they did not know where the money would come from. She had spoken to many medical students and gathered that the majority of them welcomed the Bill. They realized that through it they would have security immediately they finished their medical studies. As a member of the Miners' Welfare Commission she received every week appeal from miners who were said by their own doctors to have pneumoconiosis. The Royal Infirmary in Edinburgh had x-rayed them and the doctors said they were suffering from the disease. Yet when they went before the Manchester Board they were told they had not got it. There should be some definite work of research in relation to that disease and its relation to nystagmus.

Extreme Dislike

Col. ELLIOT said that if Miss Herbison deceived Mr. Westwood into the idea that the doctors were wholeheartedly in favour of the Bill she would encourage him to build on wrong foundations. He would not find that the medical students who they graduated were any more in favour of the Bill than the practitioners, who by an overwhelming vote had shown their extreme dislike of its provisions. If, however, Mr. Westwood was willing to accept a decision in Committee on the doctor's right of appeal, this Bill would be a much better Bill than it trailed at the heels of the English Bill. He asked Mr. Westwood or Mr. Buchanan to explain why the Hetherington Report had been thrown overboard. No single medical association and no county town or burgh had asked for the hospital proposals in the Bill. The Hetherington Report said there should be grants to the voluntary hospitals, which should be left under the control of the voluntary hospitals board. The Report said no difficulty about combining that with a system of public control. Mr. Westwood had referred to the Highlands and Islands system. All accepted that. It was small but well adapted to the circumstances. To carry on that service the Government had not found it necessary to nationalize a single hospital. The hospitals in the Highlands and Islands were left under local control. Miss Herbison had referred to defects in the provision for investigation of pneumoconiosis and other miners' ailments but she was complaining against action which was carried out by public bodies. Under a public body there would be research but the orthodox interpretation of research was often wrong. That was the danger of frozen systems such as the Government was planting on medical education and medical practice in Scotland. Mr. Westwood's attitude was that if it was difficult to fit the hospitals into the scheme, so much the worse for the hospitals; he was saying, "let the scheme go through we will jam the hospitals into it."

Mr. WESTWOOD intervened to say that in his consultation he had reached complete agreement with universities, doctors, and local authorities, and that so far as his hospital proposal was concerned the only objectors had been the representative of voluntary hospitals.

Dr. MORGAN said that although Col. Elliot pretended the unorthodoxy was found in the voluntary hospitals these had become the home and basis of orthodox medicine.

Col. ELLIOT asked whether trade union M.P.s would be happy if their unions were to be overridden by a body of which the members were chosen by the Secretary of State, who would not always be a Socialist. He read the seventh schedule of the Bill to show that this applied to the Scottish medical practice committee. He said the proposals in the Bill enforced a rigid system which would be to the disadvantage of the patient and would militate against the prosperity of Scottish schools of medicine.

Deductive and Inductive Research

Dr. MORGAN said the speech of Col. Elliot was frivolous and facetious. He was particularly glad that the Secretary of State for Scotland would have medical research in his own hands. Dr. Morgan had been afraid that Scottish research would fall under the patronage of the English Medical Research Council. In that council orthodoxy could be seen in excess. The rebels had not a chance of expressing his views or of getting into the inner counsels of medical research. He remarked that

Scotsmen tended to conduct research on deductive rather than on inductive lines, whereas in Great Britain now the great tendency in medical research was to do inductive research and to base theories and practical diagnosis on facts. Medical research in Great Britain had practically not touched upon the problems of immunity and why certain people were protected against certain diseases and others were not. He felt the Bill was a good Bill. Many assistants under contract to doctors were now in doubt because doctors would be compensated for the goodwill of their practices. Would the assistant be allowed to remain in that district and practise?

Mr. THORNTON-KEMSLEY said the Opposition accepted the desirability of regional organization and agreed that Scotland was more suited for it than was England because of the disposition of the teaching hospitals. There could be no adequate justification for placing these in a position inferior to that granted under the English Bill in regard to administration and the conservation of their endowments. The rules and regulations made by the Secretary of State or by the Regional Hospital Boards would subject the day-to-day actions of the Boards of Management to a remote and impersonal control which was unwarranted. In no instance under the Bill was revision made for the election by people in the locality of representatives to represent them on the Boards.

He urged that existing facilities for the treatment of private patients, particularly in mental institutions and in nursing-homes run by organizations such as the Officers' Association, should not be interfered with as little as possible. The feeling of the doctor or the care and welfare of his patient without outside interference might disappear altogether for lack of the stimulus of vigorous private practice. The hazard of competition with the State medical service might make it unlikely that many doctors would take the risk of remaining outside the scheme. If that occurred throughout Scotland the vast majority of doctors would owe their first allegiance to the State instead of to the patient.

Mr. CARMICHAEL, while welcoming the introduction of the Bill, criticized the provisions for boards. During recent years in Scotland the tendency had been to hamper or cripple the local authority. He, from the number of problems he had to face, had to be guided largely by the permanent officials. The medical profession under the Bill would, in the long run, have more say in the developments of the medical service in Scotland than they had had in the past, but there would be too many committees working under the guidance of the Secretary of State. Under the Bill the Secretary of State had power to refuse to publish any reports of these committees. There was no permanent link to ensure a constant movement forward in unison of the hospital board and the regional board, and the link with the local authority which was responsible for attempting to check tuberculosis in the home was not very sound. How would regional boards be able to check mismanagement by a medical superintendent who had not the courage to handle his staff or by matrons who could be very hard to the patients and to the staff?

The Mental Hospitals

Major NIALL MACPHERSON doubted whether local authority representatives would be in a majority on the boards of management for local hospitals. Had the Government so little confidence in the good sense of the people as to assume that Mr. Westwood alone could provide hospital and specialist services? Could not a scheme for voluntary co-operation between hospitals have been worked out which would have commanded support? It would have been possible to follow one of the schemes drafted by the British Hospitals Association. Only because the hospitals had seen the English Bill driven through the House of Commons had they come to the conclusion that they had better give way. That was not their real view. Mental hospitals so far had not been mentioned in the debate. There were more beds in mental hospitals in Scotland than in general hospitals. The independence of these mental hospitals should be maintained. He instanced the Crichton Royal Hospital, about 58% of whose patients were private patients; only 35% of those private patients came from Scotland. It was essential in the mental hospitals to allow the patients to choose where they would go. Control of the medical profession from the disciplinary point of view should be in the hands of the profession. It should be for the citizens, through the local authority, to say whether medical services were adequately manned. That was the way the Highlands and Islands scheme worked.

Multiplicity of Mentions

Col. GOMME-DUNCAN said the Secretary of State was mentioned in the Bill no fewer than 279 times as taking some form of power or authority. This was a travesty of democratic

government. The tribunal set up by Clause 41 to deal with complaints against doctors or dentists was a glaring example of the immense powers of the Secretary of State. He appointed the chairman and members, and any appeal from the tribunal was to the Secretary of State. He could not see why medical officers should be denied the fundamental right of appeal to an independent court of law. The tribunal would have what was tantamount to the power to strike a doctor or a dentist from the roll of his profession. A tribunal with such a power should be strengthened considerably on the professional side.

Mr. MALCOLM MACMILLAN said he felt justifiable pride in the Highlands and Islands medical service, but that service did not measure up to the requirements of to-day. Two years ago he had met representatives of all the doctors in the Western Isles. They were unanimous for the improvement and extension of those services and for the principle of a national health service. They were most anxious that the State should be in control of the national service and not the local authorities or some mixed control.

Sir THOMAS MOORE said the Bill followed slavishly the many objectionable characteristics of the English Act. Mr. Westwood must be prepared to accept a large number of amendments before Scotland would accept the measure. His friends did not believe that regional boards could adequately replace the local management boards nor that individual endowments should be handed over to an impersonal endowments commission.

Mr. RANKIN said the House was faced with a clear-cut issue of whether the Government was to allow a system of *laissez-faire* in the practice and organization of medicine to continue or whether it was to introduce a planned system. The medical profession had nothing to fear under the Bill. He remembered when nearly every doctor in Glasgow lived over his consulting-room. After the passage of the Act of 1911 these doctors acquired suburban homes with motor-cars and retained only their consulting-rooms in Glasgow. He asked why the British Medical Association refused to publish the figures of the vote which it recently took on the attitude of doctors to the scheme (see p. 957). He criticized the Bill because it separated the health services of the country into compartments and left co-ordination to co-operation between individual units.

Mr. JOHN HENDERSON said that as a manager of the Victoria Infirmary in Glasgow he had been amazed at the work which these voluntary institutions did. On the appointed day the staffs and boards of management of 220 voluntary hospitals were going to be sacked overnight.

Cmdr. GALBRAITH said the medical profession had pressed for years for a greatly extended medical service, and many of the constructive proposals in the Bill came from them. The opposition of that profession arose from the feeling that the best had not been made of a great opportunity. Under the Bill no longer could the doctor serve of right in a part of the country where he knew the people and would give his best service. He could be prevented by the Medical Practices Committee from serving in partnership with those with whom he desired to serve. The Bill was purely a bureaucratic scheme and left the machine entirely under official control.

Government Reply

Replying to the debate Mr. BUCHANAN said the discussion had been well conducted and thoughtful. He noted that both sides of the House favoured a comprehensive national health service. The clash arose over the form of the change. The Government had been charged with creating a body which was less democratic than the present system, but he doubted whether there was such a thing as a voluntary hospital. Most of these hospitals had received grants from the State. Under the system planned by Mr. Willink these grants would have gone up to nearly 70%. Where then was the voluntary principle? The voluntary hospitals had the right to dismiss any doctor. He agreed that the hospitals of Glasgow had great records, but no man should say that even they were voluntary. Every man in every Glasgow shipyard and factory had to suffer a deduction from his wages each week for the hospitals. In actual practice no man dared refuse. The hospitals had ceased to be voluntary because of compulsory deductions and State grants, and the doctors connected with the voluntary institution could be dismissed any day without even an appeal to the Secretary of State. The men elected to these boards would never dismiss unless they had a sound case.

As for the teaching hospitals, the trouble started when one tried to define them. The Royal and Western Hospitals of Glasgow had been quoted. He referred also to two other great hospitals, Stobhill and Mearns Kirk Hospital for tuberculosis treatment; there was none better in the country for treating patients or teaching. Who was to say that even in country hospitals there was no capacity for teaching? The Government contended that to leave out 230 hospitals from this great new

experiment—almost half the total—would make a sham of the whole scheme. It must not do what was done in the days of the old poor law by leaving out the best and taking only the worst. The teaching hospitals had been given a status which in most respects would meet their requirements. The Bill said that some endowments might have ceased to have the effect that the donors wished. In the new plan the Government could say to a hospital which now in part treated cancer and in part ear, nose, and throat diseases that it preferred in the interests of a" to have the work concentrated in one hospital instead of being spread over three or four. In that case there was nothing wrong with a neutral body and endowment commission transferring endowments given to a hospital for that purpose.

Salary and Capitation Fee

The idea that a doctor would not perform his duty because he received a salary was not fair to the profession. Love of the profession and love of the work would not be dimmed either by a salary or by a capitation fee. He wanted to see the sale of practices abolished. It had not always redounded to the credit of the medical profession, and he knew instances where practitioners who wished to settle in Scotland had been unable to afford the money to do so. One of the most disgraceful things he had known had been to see young doctors begging the money with which to set up practices and frequently finding, after they had paid for them, that the practices were not what they had thought they were. On this question the Government took the stand that a salary and a capitation fee were the best way of securing freedom for doctors.

Mr. Carmichael had criticized the Government for not giving sufficient power to local government, but Mr. Carmichael had also asked that there should be some form of workers' control. The doctors were the workers in this case, and they must be given some rights. The doctors had been consulted, and on the whole they did not desire the local authorities' set-up. The words of the Bill since its introduction last session had been altered so as to provide that people would have the choice of going from one place to another for a dentist. The Government wished in the field of health to make every resource available to the humblest sections of the community. It was not a question of doctrine, but a genuine theory that the sick ought to be cared for as never before. Mr. Westwood had met the doctors and had compromised. Mr. Buchanan hoped to continue to compromise.

The amendment proposed by Mr. Reid was rejected by 273 to 123 and the Bill was read a second time. It was then committed to a Standing Committee, and the money resolution attached to it was passed through committee of the whole house.

Diphtheria Immunization.—Returns from all but a few local authorities in England and Wales for the year 1945 show there were 4,410 notified cases of diphtheria and 33 deaths among immunized children under 15 compared with 8,780 cases and 558 deaths among children not immunized.

Hospital Libraries.—Mr. BEVAN said on Nov. 28 that he hoped to see library facilities developed in all hospitals within the National Health Service as and when possible. Details would have to be worked out at a later stage by the Regional Hospital Boards and Hospital Management Committees.

Mass Radiography.—Mr. BEVAN told Dr. Comyns on Nov. 28 that mass radiography units had been allotted to the county councils of London, Middlesex, Surrey, and Essex. The first two began mass radiography at the end of 1943, Surrey County Council at the end of 1944, and Essex County Council early in 1945. A further allocation of apparatus to selected authorities prepared to operate it, including West Ham Borough Council, was to begin soon.

Willesden General Hospital.—Mr. HARDY inquired on Nov. 28 whether Mr. Bevan knew that the committee of the Willesden General Hospital, a voluntary hospital, refused to set up a consultative committee in defiance of his advice to all hospital authorities. Mr. BEVAN said he was drawing the attention of the hospital authority to the recommendation he had already made that there should be a nurses' representative council in every hospital. He was inquiring into the diet of nurses at this hospital as he was anxious that nurses should be well fed.

Tied House.—An application from the L.C.C. for approval for the erection of a doctor's house on a vacant site at St. Helier Estate, Morden, is under consideration.

Free Choice.—On Dec. 5 Mr. BEVAN told Mr. Carson that when the new Health Service came into operation, all non-contributory old age pensioners would have the same free choice of doctor as everyone else.

Birth and Adoption Certificates.—Mr. BEVAN hopes to introduce this session a short Bill making it possible, as in Scotland, to issue shortened birth certificates and also shortened extracts from the Adopted Children Register which will contain no reference to parentage or adoption.

Universities and Colleges

UNIVERSITY OF WALES

The following candidates at the Welsh National School of Medicine have satisfied the examiners at the examination indicated:

M.B., B.Ch.—*Pharmacology*: N. V. Chivers, P. R. C. Davies, B. H. Evans, Ruth E. Lewis, N. J. Morgan, C. L. Perry, E. Thomas. *Pathology and Bacteriology*: Mary Smith. *Hygiene*: D. R. Bowen, *Elizabeth B. Butler, Joan P. Ciantar, A. C. Coulthard, A. J. Dark, G. C. Davies, H. B. Davies, Janet Dean-Jones, J. A. Emanuel, G. S. Foster, T. Griffiths, H. Harrop-Griffiths, C. Havard, C. H. L. Howells, T. R. Hunt, D. W. James, Beryl H. Jones, H. E. Jones, Margaret E. B. Jones, Margaret O. Jones, W. R. King, J. G. Leopold, J. B. R. Lewis, *L. T. Lewis, Margaret I. Morgan, Vivien J. Parker, F. I. Powell, L. T. Rees, G. G. Richmond, Mary Smith, S. Solomon. *Medicine*: Clare G. M. Dillon, R. L. H. Jones, Goronwy Owen.

* With distinction.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following medical degrees were conferred on Dec. 4:

M.D.—M. O'C. Drury, L. Li. Griffiths, R. J. S. Wilson.
M.Ch.—H. A. Daniels.
M.B., B.Ch., B.A.O.—J. R. Bannister, D. S. N. Darling, Daphne M. N. M. Dooley, M. E. Eppel, R. Esler, J. P. R. Farrell, E. M. H. Forster, D. S. Kearon, P. J. MacCarthy, Esther M. McMillan, Eileen Moriarty, D. T. Li. Nash, S. J. Poets, B. Redmond, D. L. Robinson, D. Anton-Stephens.
L.M.D., L.Cit., and L. Oaster. Sc.—I. Citron.

Medico-Legal

LEUKAEMIA AND WAR SERVICE

A driver in the Royal Army Service Corps was one of those whose duties took them to Belsen Camp soon after it was discovered. He stayed there a few days, and seven days later he fell ill with an acute type of leukaemia. He was flown to England but died in about four weeks. His widow claimed a pension. Before 1944, she would have had to prove that the death had been attributable to war service, but by the Royal Warrant which came into force at the end of 1943 claimants are in a much stronger position, for the Minister must now prove that the prescribed conditions have not been fulfilled—i.e., that the death must have been due to or hastened by a wound, injury, or disease attributable to war service, or the aggravation by war service of a pre-existing trouble. The claimant is given the benefit of all reasonable doubt. Moreover, as leukaemia was not noted in any medical report made on the driver at the beginning of his service, the widow had a presumption in her favour that it was attributable to his service. The Minister and the Pensions Appeal Tribunal both found against her and she took the case to the High Court.

Mr. Justice Denning's judgment (for a report of which we are indebted to the British Legion) shows how heavily the scales are weighted in favour of the claimant in a Service pension case. The Medical Services Division of the Ministry had stated that leukaemia was a condition in which there was an overgrowth of the white cells of the blood; there was no evidence that the disease was caused by any known organism; the changes which occurred were generally regarded as neoplastic, affecting the white-blood-cell-forming tissues; and the disease ran a characteristic course which in the acute type was rapidly fatal. This, said the judge, told the court nothing about the cause. The Division concluded that leukaemia was not a condition of which the onset or progress could be regarded as affected by conditions of service, including those which the widow alleged. If, said the judge, the earlier part of this opinion had contained material sufficient to warrant such a conclusion, he would have been unable to interfere with that evidence, but he found nothing to do so in any way. Considering that the disease had shown itself after the man had stayed in Belsen Camp, and in view of the strong presumption created by the absence of any mention of it in an initial medical report, the medical evidence against the claim must be particularly cogent in order to defeat it, and must establish clearly that all external causes could be excluded. This it had not done. He therefore reversed the finding of the tribunal and granted the pension.

Sir James Berry, F.R.C.S., who died on March 17, left £38,746 gross, with net personality £38,514. He left one-sixth of the ultimate residue of his estate to be divided between the Royal Free Hospital, Royal College of Surgeons, Royal Society of Medicine, Medical Society of London, the Commons, Open Spaces and Footpaths Preservation Society, the Geological Society, the Bucks Archaeological and Architectural Society, and the Society of Antiquaries.

No. 48

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital statistics in the British Isles during the week ended Nov. 30.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or return available.

*Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary fever for England and Wales, London administrative county, and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

It is still not possible to publish the return of births and deaths for Eire for the weeks ended Oct. 26, Nov. 2, 9, 16, 23, and 30.

EPIDEMIOLOGICAL NOTES

Epidemic Gastro-enteritis

Up to Dec. 15, Leicester City General Hospital had reported the deaths of 15 infants among 36 cases of gastro-enteritis. Cases first appeared in two nurseries about Sept. 6. An explosive spread began on Dec. 4 and involved an additional emergency nursery; all three nurseries (45 beds) have now been closed. The cases have begun about the fifth day of life and have not responded to penicillin or sulphonamides; deaths have occurred in the second week of infection. There have been associated mild symptoms in mothers and in the nursing staff. No pathogens have been isolated, but the investigating bacteriologist is said to be satisfied that the infection has not arisen from milk.

The Cowley Road Hospital at Oxford has had since July 75 cases of gastro-enteritis, with no deaths, all restricted to one 36-bedded block. The attack rate was July 19%, August 38%, September 26%, and October 76%; about 10% of mothers developed symptoms after returning home. The infection was first noticed in the mothers and only subsequently observed in babies. Almost all the staff of this block have been attacked. Wards have been closed for fourteen days from Dec. 7, and so far no causative organism has been isolated. One mother was transferred to cubicle-isolation under rigid conditions in another hospital; four out of a staff of seven specially trained in barrier nursing became affected.

Preston has had 18 (6 recent) deaths out of about 200 babies born in the wards in the last six months; 21 mothers and babies were sent home when the wards were closed on Dec. 14.

Reports of 4 further deaths from Windsor and Glasgow may or may not be significant. Earlier in the year Leeds City Hospital had 15 deaths and the maternity wards there were closed for three weeks.

Discussion of Table

In England and Wales the only large changes in the notifications of infectious diseases were increases in measles 577 and whooping-cough 105. Small decreases were recorded for scarlet fever 19, diphtheria 18, and dysentery 11.

The largest of the local rises in the incidence of measles were Durham 191, Lancashire 116, Warwickshire 69, and Surrey 32, while the biggest decrease was Yorkshire West Riding 90. The trends of whooping-cough fluctuated, and the most important increases in notifications were Essex 31 and Surrey 23. The only change of any size in the returns for scarlet fever was an increase of 23 in Middlesex. A small decrease in cases of diphtheria was recorded in most areas, the only exception being London, where the cases rose from 12 to 24. The largest centre of London also had 17 cases of dysentery.

In Scotland increases were recorded in the notifications of whooping-cough 48 and measles 30, and decreases were reported for scarlet fever 29, diphtheria 22, and acute primary pneumonia 20.

In Eire the chief features of the returns were decreases in diarrhoea and enteritis 12, and measles 12, and an increase in the cases of whooping-cough 13. The incidence of poliomyelitis remains unchanged with 16 notifications.

In Northern Ireland a large increase was recorded in the outbreak of measles in Belfast C.B.; the cases increasing from 47 to 106. Scarlet fever was slightly more prevalent in the country, the notifications increasing by 8.

Week Ending December 7

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,277, whooping-cough 1,783, diphtheria 313, measles 6,466, acute pneumonia 677, cerebrospinal fever 40, dysentery 76, acute poliomyelitis 14, paratyphoid 6, typhoid 7.

From January, 1947, a new two-monthly *Nutrition Bulletin* is being published in printed form by the Central Council for Health Education, Tavistock House, Tavistock Square, London, W.C.1. The subscription rate is fixed at 3s. per annum. The *Bulletin* will deal not with the basic principles of nutrition but with the theory and practice of the application of these principles to social betterment. It will, in brief, be concerned with the growth of the various nutrition services, the principles underlying public instruction, the food habits of the community, and the place of diet in the national health. The advisory editorial group which will direct the policy of the new publication will carry on the bulletin service established by the Children's Nutrition Council.

Medical News

Abstracts of World Medicine and Abstracts of World Surgery, Obstetrics and Gynaecology will make their first appearance in January, 1947. These two new journals are being published monthly by the British Medical Association, the first at an annual subscription of 3 guineas and the second at 2 guineas. Applications for subscription should be sent to: The Publishing Manager, *British Medical Journal*, B.M.A. House, Tavistock Square, London, W.C.1.

A lecture to commemorate the centenary of the first public administration of ether in Europe will be delivered by Dr. Massey Dawkins, at University College Hospital Medical School, Gower Street, W.C., on Saturday, Dec. 21, at 4.45 p.m.

A series of six lectures on "The Applications of Atomic Physics in Medicine" will be given by Prof. W. V. Mayneord at the British Institute of Radiology, 32, Welbeck Street, London, W., on Wednesdays at 5 p.m., from Jan. 1 to Feb. 5, both dates inclusive.

At a special meeting of general practitioners of the East Ham area held on Dec. 4, 1946, under the presidency of Dr. J. Stanley Thomas, J.P., a presentation of an illuminated scroll was made by Dr. R. V. Brews, J.P., to Mr. F. J. Ashford, the Clerk of the East Ham Insurance Committee. The scroll, which was signed by every general practitioner in the area, reads: "... to commemorate his 25 years' service and as a tribute not only to his administrative ability, but to his invaluable help and kindness to the whole profession."

Sir Drummond Shiels, M.B., who was Parliamentary Under-Secretary for India in 1929 and for the Colonies in 1930-1, has been appointed a member of the Council to further the economic and social development of the Colonial Empire.

The Empire Rheumatism Council recently held a dinner in honour of European delegates to the International League against Rheumatism, Lord Horder being in the chair. Among those present were the following members of the medical profession. Prof. Jarlov (Copenhagen); Chief Physician Edstrom (Lund); Dr. Kalbak (Copenhagen); Dr. Loring Swaim (Boston); Dr. B. Schlesinger; Dr. W. S. C. Copeman; Dr. E. R. A. Merewether; Mr. A. G. Timbrell Fisher; Dr. F. D. Howitt; Dr. Oswald Savage.

Because of the increased demands upon Members made by the present Parliament, Sir Ernest Graham-Little, Independent M.P. for London University, has resigned the chairmanship of the University External Council, which he has held continuously for nearly 25 years.

There are to be two medical consultants for the Highland area of Scotland. Dr. Thomas Scott, Inverness, has already been appointed, and on Dec. 4 a panel under the chairmanship of Prof. R. S. Aitken, University of Aberdeen, selected the following list from which the second will be chosen on Jan. 7: Drs. C. R. Greig, Stanley Alstead, John R. Forbes, J. Gibson Graham, R. D. C. Johnstone, Donald R. Macdonald.

A picture library has been established by the British Red Cross for the purpose of lending reproductions of the finest pictures, both old and modern, to patients confined for a long time to hospital or sanatorium. Hospitals pay an annual subscription at the rate of 1d. per picture per week. Inquiries should be addressed to the organizing secretary, B.R.C.S. Picture Library Scheme, 14, Grosvenor Crescent, London, S.W.1.

From all parts of Scotland and from the Shetlands some 90 delegates went to Edinburgh on Dec. 6 to discuss health education in schools at a conference sponsored by the Scottish Council—the first of its kind to be held. The delegates represented medical officers of health, education bodies, and the central government departments involved. Many local meetings in various Scottish towns have recently attracted large and enthusiastic audiences. By health education is meant teaching school-children "the principles and art of healthy living" to equip them to cope with the strain of daily life. The Council has appointed a full-time medical lecturer to help in the counties, where problems of health education require a different approach from that used in the cities.

Bradford Primary Education Committee has decided to purchase Langley, Baildon, for the treatment and education of rheumatic children. The house will provide accommodation for 35 children.

Dr. William Langham Garner, of Bournemouth, who died on March 16, left £24,165. He left £2,000 to Guy's Hospital to help "sufferers from cancer."

After 36 years of distinguished service in the United States Public Health Service, Dr. Lewis Ryers Thompson, Assistant Surgeon General in the Bureau of State Services, has retired. He has been succeeded by Dr. Hermann E. Hilleboe, who has been Chief of the Tuberculosis Control Division since its inception in 1944.

The British Legion Convalescent Home at Churchill Court, Sevenoaks, Kent, which has accommodation for fifty ex-Service men and women of the 1939-45 war, is intended for those in need of (a) convalescent treatment for two or three weeks to enable them to recover from a severe illness; or (b) a fortnight's holiday to prevent a breakdown in health. Applications for admission are made through the local British Legion Service Committee, or by application to the British Legion and United Services Fund Benevolent Department, Pall Mall, London, S.W.1.

The Thistle Foundation, whose purpose is the medical treatment and psychological rehabilitation of Scotland's most gravely disabled men, is not affected by the National Health Service Act. Its president, Mr. Tudsbury, C.B.E., explained at the recent annual general meeting that it was essentially a housing scheme and not a hospital. Contributions had suffered somewhat since the introduction of the Bill. The total amount now surpasses £382,000, and donations come in from all parts of the world.

A team of workers connected with the medical and public health services of Ceylon has arrived in this country, under a scheme arranged between the Ceylon Government and the National Association for the Prevention of Tuberculosis, to study the latest methods of tuberculosis control and of the treatment and after-care of tuberculous patients in Great Britain. The team consists of one doctor, Dr. J. R. Wilson, who has already specialized in tuberculosis; one health officer, Mr. W. Clement Fernando, who will be in charge of a training centre for sanitary inspectors, social workers and teachers on his return and is especially interested in the social welfare side; and two nurses. The Singhalese team is expected to make a stay of about six months, and will be given opportunities of visiting and working in various institutions, clinics, and centres connected with tuberculosis work, and of meeting specialists in the different spheres of that work.

The future of King Edward's Hospital Fund for London was referred to by Lord Catto at a meeting of the Fund's General Council on Dec. 10. The Fund would be in a similar position to that of the Rockefeller Trust, and would be used for the "support, benefit, or extension of the hospitals of London." With the disappearance of the distinction between voluntary and publicly provided hospitals both types would come within the scope of the Fund. The improvement of hospital catering, provision of special mattresses, and the establishment of a recovery home for diabetics are among the purposes to which the Fund has recently been put. Total disbursements for hospitals during the year were £364,000, and in addition grants amounting to £7,500 were made from the radioltherapy fund.

The first number of the *Journal of General Microbiology* of the newly founded Society for General Microbiology, whose president is Sir Alexander Fleming, will appear in January, 1947, under the editorship of Drs. B. C. J. G. Knight, and A. A. Miles. Prof. W. B. Briely and Drs. T. Gibson, A. T. R. Mattick, Kenneth Smith, A. W. Stableforth, and D. D. Woods will be associate editors. There will at first be three numbers a year; the subscription is 50s. Papers for publication should be sent to Dr. A. A. Miles, National Institute for Medical Research, Hampstead, London, N.W.3; other communications to the Cambridge University Press, Bentley House, 200, Euston Road, London, N.W.1.

The first annual report of the Liverpool Cancer Control Organization describes its development since 1939, and the activities of its first year as an incorporated body. The Organization was founded to acquire the radium previously held by several different institutions in Liverpool and to provide a complete cancer service on a regional basis. As an independent corporation it provides a unified administration which transcends local authority boundaries. It contracts with local authorities to carry out their obligations under the Cancer Act and makes arrangements with the various institutions which can provide appropriate services. Although much of the work of the Organization will presumably be taken over by the National Health Service, the governing body believes that it has constructed a service and an administration which should fit well into the new pattern, and that it has provided an interesting and instructive experiment in a new type of hospital administration. The Organization, it is thought, may well have a useful future in independent non-official activities, including research.

Since the calling up of women for enlistment in the Women's Auxiliary Forces has ceased the regulations requiring information to be supplied about the tuberculosis history of women called before medical boards have been revoked by the Public Health (Tuberculosis) Regulations, 1946.

Alfred Beuthin Danby, F.R.C.S., F.R.C.O.G., of Kidderminster, late obstetric surgeon to Birmingham Maternity Hospital and past president of the Midland Obstetrical Society, left £16,508. Matthew Clayton-Mitchell, F.R.C.S., of Norfolk, Senior Medical Officer of the Gambia, British West Africa, left £10,167. Sir Arthur Lisle Ambrose Webb, K.B.E., C.B., C.M.G., late R.A.M.C., of Balcombe, Sussex, secretary and treasurer of Queen Mary's (Roehampton) Hospital 1933-42, left £7,737.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Antology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate, Westcent, London*. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecta, Westcent, London*.

R.M.A. SCOTTISH OFFICE: 7, Drumshugh Gardens, Edinburgh

ANY QUESTIONS?

Threadworms in Infants

Q.—*What is the best method of dealing with threadworms in an infant aged 2 years?*

A.—The best drug to date is gentian violet. It is given in enteric-coated capsules, the dose being 1/6 gr. (11 mg.) per year of apparent age, each day for about a week. A second similar course is given after one week's rest. The child in question could have two capsules, one after breakfast and one after supper, each containing 1/6 gr. It is a good plan to apply a little ung. hydrarg. ammon. dil. round the anus at night, keep the nails short, and let the child wear pyjamas or knickers to prevent scratching. If a relapse occurs, it may be worth while having other members of the household examined (by anal swabs); one of them may be a symptomless carrier.

Dinitrophenol

Q.—*Is it ever permissible or advisable to give dinitrophenol for the reduction of obesity?*

A.—Dinitrophenol is a dangerous drug which should never be used. It causes cataract in a proportion of patients. This is an absolute contraindication.

Coombs' Test

Q.—*How is Coombs' test for haemolytic disease of the newborn performed? Where can I obtain the anti-human-globulin serum required for the test?*

A.—For the performance of the direct Coombs' test a few drops of blood taken from the newborn infant, from the cord or from a heel-prick, are dropped into citrate. The cells are suspended in enough saline to give a suspension of 1% or less and are centrifuged. This washing with saline is repeated twice more and the cells are then again suspended in saline to give approximately a 5% suspension. A drop of this is mixed on a tile or slide with a drop of suitably diluted anti-human-globulin serum, allowed to stand for a minute, and then rocked extremely slowly. In positive cases obvious macroscopic agglutination usually appears in a minute or two, and in any case within ten minutes. It is wise to put up two controls, one using saline in place of antiserum and the other using normal human red cells in place of the baby's cells. The appropriate dilution for a given batch of antiserum will have been determined previously by titration. A positive result means that antibody globulin, presumably maternal, is present on the surface of the child's cells. In newborn infants, using a reliable serum, the test appears to be pathognomonic of haemolytic disease. It is very convenient for determining rapidly whether a given child ought to be transfused, but it does not indicate whether the antibody concerned is in fact common anti-Rh (anti-D). This should be ascertained, preferably before birth, by testing the mother's cells and serum, and blood of appropriate type (Rh-negative or other) should be made available for transfusion.

The indirect Coombs' test may be used for detecting minute traces of maternal antibody. The maternal serum is incubated with an equal amount of 2% suspension of Group O Rh-positive (preferably R₁R₂) cells for half an hour. The cells are then washed and tested as described above. Agglutination

shows that antibody is present in the maternal serum. Anti-human-globulin serum for these tests is not yet generally available but will probably be so in a few months' time. Regional blood transfusion officers are kept informed of the supply position.

De-sterilization

Q.—*A patient has had four Caesarean sections, producing five healthy children. She was sterilized after the birth of twins four years ago. She now wishes to have another baby, and is to undergo an operation to make this possible. What are the chances of her becoming pregnant?*

A.—The chances of the operation being successful depend very much on what type of sterilization procedure was carried out previously. If the continuity of the tubes was not destroyed and the abdominal ostia were merely buried extra-peritoneally, it may be possible to restore the anatomy to normal. If the technique employed was resection of the intramural parts of the tubes and the cornua of the uterus, then reimplantation of the outer ends of the tubes would offer a reasonable chance of success. If, however, the middle portions of the tubes have been removed then it will be extremely difficult to restore their continuity and a successful result is only a remote possibility. In general, the chances of success should be somewhat higher than those attending similar plastic operations on tubes obstructed by previous infections because the operation will be on healthy rather than diseased tissue.

Chemoprophylaxis of Rheumatic Disease

Q.—*American workers claim that the daily use of sulphamides over long periods by young people who have had one or more attacks of rheumatic fever will reduce the chances of recurrence, and therefore the risk of crippling heart disease. Are these claims upheld by British workers?*

A.—A Medical Research Council committee has been engaged on a repetition of American work on this subject but has not yet published its findings. As regards the rationale of the treatment, Dr. Cruickshank, who has recently visited the U.S.A., has pointed out (*Monthly Bulletin of the Ministry of Health*, July, 1946, p. 146) that numerous studies indicate that rheumatic fever follows an attack of streptococcal tonsillitis or pharyngitis usually after an interval of ten days to three weeks. "Only a small proportion of those initially infected develop rheumatic fever, but these susceptible individuals, once affected, are prone to recurrent attacks if they are again infected by the haemolytic streptococcus. It therefore seemed worth while to prevent, if possible, rheumatic subjects from acquiring the secondary streptococcal infection which reactivates the rheumatic disease. . . . While any patient who has had one attack of rheumatic fever might be considered suitable for chemoprophylaxis, a fair proportion of children do not develop cardiac complications. Prophylactic use of the drug might therefore be limited to children who have already had two attacks and to those who have had one attack accompanied by rheumatic carditis. Sulphadiazine, sulphamezathine, or sulphanilamide are the drugs of choice."

Tonicity of Penicillin Solutions

Q.—*To minimize the discomfort of injection the solution used should be isotonic. A solution of 100,000 units of penicillin in 5 ml. of water is hypertonic, and in saline solution will be even more irritating to the tissues. Why, then, is normal saline solution used to dissolve penicillin for intramuscular injections?*

A.—The tonicity of a penicillin solution depends not only on its concentration but on the impurities in the penicillin. What would be true of one sample would therefore not necessarily apply to another. In so far as isotonicity is important it would be helpful if manufacturers stated for each batch the concentration of it in solution which is isotonic; the amount of sodium chloride needed to render a weak solution isotonic could then be added. It is true that the concentrated solutions now used for giving large doses intramuscularly in a small volume are usually hypertonic; such solutions should therefore be made in distilled water and not in saline. Many users have always done this and still do so.

Lövset's Manœuvre for Breech Delivery

Q.—Is Lövset's manœuvre for breech delivery recommended? If so, will you please describe it.

A.—This manœuvre is concerned with the delivery of the shoulders and arms and was described by Jörgen Lövset, of Bergen (*J. Obstet. Gynaec. Brit. Emp.*, 1937, 44, 696). It is based on the fact that, owing to the inclination of the pelvic inlet, the posterior shoulder enters the pelvic cavity before the anterior—i.e., when the trunk of the child is delivered so far that the inferior angle of the scapula is visible, the posterior shoulder is below the sacral promontory whereas the anterior one is still behind or above the pubis (Fig. 1). At this stage in the delivery, and with the patient in the lithotomy position, Lövset advises rotation of the trunk of the baby through 180 degrees, the back passing anteriorly (Fig. 2). This brings the posterior shoulder to the front, but on a lower plane so that it appears below the pubic arch

FIG. 1

(Fig. 3). From this position it either delivers itself spontaneously or it can be lifted out by one finger placed in the bend of the elbow. The body of the child is now rotated 180 degrees in the opposite direction, thus bringing the other arm to the anterior position again. This also appears at a lower level and can be lifted out from beneath the symphysis. If the rotation is carried out before the posterior shoulder is below the sacral promontory, the manœuvre will not succeed. It is easier to perform when the child is well-developed and firm than when it is small and under-developed. It is applicable no matter whether the foetal arms are flexed, extended, or in the nuchal position.

The advantages claimed for the method are that it avoids fracture of the foetal humerus and that it is easier and more efficient than the traditional methods of bringing down the arms. On the other hand it involves risk of fracture of the clavicle and of damaging the abdominal viscera unless care is taken to grip the foetus by the pelvic girdle. If the shoulders are tightly wedged the vertebral column is exposed to an extreme rotatory strain. The method is not widely used in this country although it has some enthusiastic advocates. It is unnecessary when the arms are flexed, but if they are extended it is a useful method to have "up one's sleeve." If applied correctly it may succeed when other methods have failed.

FIG. 3

Mineral Oil Dermatitis

Q.—A young adult male developed oedema of both hands and wrists, with urticaria of the face and neck, after working with diesel and other oils. Can you suggest treatment, and should he seek other work? Does strong sunlight make the exposed skin more sensitive to these oils?

A.—If this condition can be definitely attributed to contact with mineral oil, the man will be well advised to avoid further exposure. The part played by sunlight in the aetiology of the

condition is uncertain. The immediate treatment would be that appropriate for an acute dermatitis. Attempts at desensitization have proved disappointing.

Bovine Tuberculosis

Q.—How many deaths each year are due to bovine tuberculosis? Is it more common in the towns or in the country? To what extent is milk pasteurized in the towns as compared with country districts?

A.—There are no exact statistics relating to either bovine tuberculosis or the pasteurization of milk. Typing demands considerable time and skill and is not done as a routine, so our knowledge of deaths from tuberculosis of bovine origin are based on the findings of relatively small series. Using the ratios found in these series the deaths from bovine tuberculosis are estimated to be 1,500–2,000 per annum. There is a decided geographical distribution of this disease, low in the South and high in the North. The number of persons suffering from tuberculosis of bovine origin is unknown. In London and some of the other large cities practically all the milk is heat-treated while in country districts the milk is mainly raw, but between these extremes there is a considerable variation.

LETTERS, NOTES, ETC.**Aneurysm of Superficial Temporal Artery**

Mr. CHARLES MACLAY, F.R.C.S., writes from Glasgow: A man aged 23 was admitted to hospital in July, 1946. He had complained for six months of pain in front of the left ear, and of a noise in the head, synchronous with the pulse. Also he had a slight watery discharge from the left ear. On examination there was found in front of the left ear a swelling about the size of a marble, which exhibited expansile pulsation, a well-marked thrill on palpation, and a loud systolic bruit on auscultation. This swelling also bulged into the anterior wall of the external auditory meatus. The past history was that in May, 1945, this patient was wounded in the left side of his scalp by fragments of 88 mm. shell and was operated upon, but did not know if any foreign body was removed. At that time he experienced pain in front of the left ear; this lasted two weeks and then disappeared. X-ray examination showed several minute foreign bodies in the scalp but none in the immediate vicinity of the swelling. At operation, an aneurysm of the left superficial temporal artery was found. This was dissected free and removed entire. The wound healed satisfactorily, and symptoms were completely relieved.

Old and New

Dr. A. HENRY GREGSON (Cromer) writes: May I plead for greater care in claiming "new" techniques. One might remember that the "dorsal slab" for Colles's fracture was the standard treatment in the army of Napoleon I, that the mould off cheese was a common application for septic wounds in remote parts of England ninety years ago, and that the head-suspension plaster jacket for sciatica due to scoliosis is a very slight adaptation of treatment used 2000 B.C., there being a stone carving showing this method in existence.

Artificial Limbs for Women

Mr. A. W. SHAW (Rochampton House, S.W.15) writes: I would refer to Mr. C. R. Howard's communication (Nov. 16, p. 760) regarding the points in the design of the modern artificial limb referred to by your correspondent, "L. S. S. W." (Sept. 21, p. 438). Mr. C. R. Howard has, in my view, answered each point in a very satisfactory manner, but apparently he is not aware of the method employed at Rochampton in regard to the obviation of the glitter of the enamel. It is the custom at Rochampton to supply a matt finish enamel which prevents the glitter. You may decide to mention this point in view of the considerable publicity that has already been given to the subject.

Lumbar Puncture

Dr. ANDREW J. NAIRN (Burnside, Lanarkshire) writes: In obese subjects where spinal analgesia is the method of choice, it may be very difficult, if not impossible, to palpate the spine of the fourth lumbar vertebra. The iliac crest is quite readily found, but unless the correct interspace is accurately localized it will be practically impossible to locate the theca. Defining the mid-line is the difficulty. If, however, a line is drawn with iodine at right angles to the iliac crest, and another line prolonging towards the head the sulcus formed by the meeting of the two buttocks, these lines will meet over the fourth lumbar spine (if the patient is in the correct position). Thus the mid-line is accurately defined, and it is a simple matter thereafter to locate the required interspace (usually between lumbar 3 and 4) and to administer the injection.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 21 1946

British Medical Association PROCEEDINGS OF COUNCIL

Additional Meeting: Wednesday, December 11, 1946

An extra meeting of the Council was held on Dec. 11 at 12 noon. Dr. H. Guy Dain was in the chair, and there was a full attendance.

Deaths of former members of Council were reported—namely, Dr. Arnold Lyndon, Dr. T. S. Rippon, and Sir Edward Newbury Thornton (South Africa)—and the chairman was authorized to forward letters of condolence to the respective families.

Results of the Plebiscite

A statement of the figures of the plebiscite was placed before the Council. The chairman commented upon the high proportion of practitioners who had sent in returns—81.4% of the members of the profession other than those in the Services. He said that it was higher than the percentage attained in most elections, parliamentary or other. It was now for the Council to consider what action should be taken in the light of the returns.

The Council then proceeded to a detailed examination of the analyses up-to-date figures, and a debate took place on the inferences to be drawn from them and the action to be taken. On the motion of Dr. R. W. Cockshut, seconded from various parts of the Council, the following resolution was carried:

That the Negotiating Committee be advised that in view of the results of the plebiscite the Minister be informed that because of the divergence between the principles of the profession and the provisions of the National Health Service Act, the Committee is unable to enter into discussions with the Minister on the Regulations to be made under that Act.

It was further agreed that this should be a recommendation to the Representative Body, and that a Special Representative Meeting should be called for Tuesday, Jan. 28, 1947.

Again on the motion of Dr. Cockshut a hearty vote of thanks was accorded to the staff for the efficiency and expedition with which the work on the plebiscite had been organized and carried through.

On the assumption that the Representative Body would approve the recommendation set out above it was agreed to appoint a small executive whose principal work it would be to organize and hold together the profession during the coming months, and also to consider, with the best professional advice obtainable, the legal bearings of any action contemplated—a body which could act quickly in the possibly changing phases of the dispute which lay ahead.

It was decided that this executive should consist of the following: the officers of the Association; the chairmen of the Insurance Acts, General Practice, and Consultants and Specialists Committees (Dr. E. A. Gregg, Dr. S. Wand, and Mr. A. M. A. Moore), the chairman of the Panel Conference (Dr. J. A. Brown), Mr. Lawrence Abel, Dr. R. W. Cockshut, Dr. W. E. Dornan, Mr. A. S. Gough, Dr. Frank Gray, Mr. R. L. Newell, Dr. J. A. Pridham, and Dr. N. E. Waterfield.

Areas of Regional Boards

The proposed areas of the Regional Hospital Boards were considered. The chairman said that he had been asked whether, having decided not to enter into negotiations, the Council could fittingly offer criticism of any proposed arrangements, but in his view these suggested geographical boundaries might well

be considered both centrally and locally. Dr. Talbot Rogers also said that this matter should not be allowed to go by default. The regions had been delimited, not with regard to natural hospital areas as these were understood but to university centres, and it was open to consideration whether some of them were the most suitable for hospital administration. The area proposed for Bristol, for example, was very cumbersome, and to make the whole of Wales one region did not seem to be administratively very happy. Further, were 14 regions enough for England and Wales?

Mr. Abel pointed out the undue shortness of the time allowed for criticism (the Minister expected to receive any observations from the Association and other bodies within one month of the issue of the provisional proposals), and it was agreed to bring this point to the attention of the Ministry.

Attention was drawn to the question of membership of regional boards as well as of any councils or committees set up under the Act. The advice of the Association was that no member should accept a place on these bodies pending the decision of the Special Representative Meeting. It was pointed out that this was one of the problems, perhaps involving legal issues, which the Executive Committee just set up would have to consider at the outset.

Reform of G.M.C. Procedure

Mr. Dickson Wright presented a report for the General Medical Council Committee. He said that the Committee had spent a considerable time discussing the penal powers of the G.M.C. and had sent observers to a conference on the subject between G.M.C. representatives and the defence societies. A number of recommendations (30 in all) had been formulated on the basis of a joint statement prepared by the three defence societies. The G.M.C. had prepared a draft Medical Bill of 13 clauses the purpose of which would be to strengthen its position in dealing with penal cases by giving it the power to subpoena witnesses and to take evidence on oath.

Dr. J. W. Bone, a member of the G.M.C., gave the Council a summary of the draft Bill. Apart from the provisions relating to penal procedure, it was proposed that the Council should take power to visit medical schools to inspect teaching and not merely examinations as at present; also that the Goodenough Committee's recommendation be implemented, that one year's residence at hospital should be required of newly qualified practitioners. The Bill proposed to increase the number of direct representatives, at present standing at six, to nine; the recommendation of the B.M.A. Committee was that they be increased to fourteen. Dr. Bone added that there was very little that was controversial in the Bill, but if the B.M.A. Committee proceeded with all its recommendations controversial issues would be raised and there would be no effect at all except a destructive one so far as the Bill was concerned. They had been told that if this was not an agreed Bill there would be no chance even of its introduction into the House of Commons. He suggested that the present recommendations be sent to the G.M.C. and that a conference might be arranged with a view to reaching agreement on these matters.

Dr. J. B. W. Rowe suggested a joint discussion between the B.M.A. Committee and the committee of the G.M.C. which had prepared the Bill, with a view to reaching agreement as to

the points which were non-controversial, and that the points which were controversial should be extracted from the present recommendations and brought back to the Council for further discussion.

This course was agreed to, and the recommendations were approved as a basis for further discussion.

The "Closed Shop"

Dr. J. B. Miller took the chair of the Council while Dr. Dain, as chairman of the special committee in charge of the subject, presented a report on the "closed shop" issue. He said that the committee had started with a unanimous expression of opposition to any restriction being placed on members of the profession as to joining any organization. This was a simple matter so far as those local authorities were concerned which required membership of a trade union, whether affiliated or not to the T.U.C. But difficulties arose when the resolution of the authority required membership of a trade union or professional organization, for a position might arise in which the Association would have to advise its own members not to apply for or accept an appointment which required the applicant to be a member of the B.M.A., and if such a member nevertheless accepted the appointment the ethical rules might have to be invoked with a view to his expulsion. The course of events at Willesden had to some extent changed the situation. An advertisement for a medical officer of health for Willesden which imposed the trade union condition had been refused for insertion in the *Journal*, but since that action was taken the nurses at Willesden had fought the first round of the battle and had gained the position that professional officers of that local authority should not be required to join an association of any kind. He understood that the Willesden Council had now removed its restriction.

The Secretary said that he had been in touch with the Royal College of Nursing throughout the Willesden discussion. In the result the Willesden Council, notwithstanding the recommendation of its general purposes committee, decided to drop the whole thing. The reason for its alteration of position was partly a communication from the Minister of Health to local authorities in which he stated that these matters should not be determined by the unilateral action of local authorities. Willesden had brought the issue right home.

Dr. Cockshut pointed out that Edmonton had appointed two assistant medical officers, and had required membership of a trade union. Should not their resignation be required? Dr. Waterfield said that there had been no "Important Notice," and these people had had no warning at the time, so that it would be better not to take retrospective action. The Council agreed that any action should relate to future cases and should not be retrospective.

The following was approved as a statement of policy to be recommended to the Representative Body for adoption:

(1) The B.M.A., representing the great majority of doctors and enjoying a membership of over 54,000, is the negotiating body for the medical profession, recognized as such by the Ministry of Health and the associations of local authorities.

(2) In the view of the Association it is undesirable on principle that any practitioner should be required to join any body, B.M.A. or other. The Association prefers that its membership should remain voluntary, the strength of the Association remaining an expression of the profession's confidence in its representative body.

(3) Where an authority imposes upon its officers or candidates for office a requirement of a membership of a particular body or bodies, B.M.A. or other (but excluding a medical defence society), the Association should protest to such authority and afford financial help to any practitioner who suffers as a result of accepting the advice of the Association. All advertisements for whole-time public health medical officer appointments of such authorities, submitted by such authorities for publication in the *British Medical Journal*, shall be rejected, and the profession advised not to make applications for such posts. The medical press should be asked to co-operate.

It was agreed that it was necessary to exclude from the operation of any such resolution requirements on the part of authorities that applicants should be members of a defence society; also that the Department of Health for Scotland should be coupled with the Ministry of Health in the first paragraph of the resolution.

Miscellaneous Business

On the recommendation of the Consultants and Specialists Committee approval was given to proposals for increases in the maximum fees payable under Part II of the Second Schedule of the Pensions Appeal Tribunals (England and Wales) Rules, 1943. The increases were from two guineas to three guineas for attendance of a medical witness before a tribunal and from five shillings to one guinea for medical certificates and reports obtained by the appellant.

Authority was given to the Psychological Medicine Group Committee to co-opt three additional members in order to make the committee representative of the various branches of psychiatry; and also to have at least one observer from the committee, to attend meetings of the Committee on Psychiatry and Law.

A letter was read from the British Association for the Welfare of Spastics asking the B.M.A. to appoint a representative to attend a meeting for the purpose of constituting the council of that Association on a more widely representative basis. It was left to the Orthopaedic Group Committee to nominate a representative. Incidentally some members of the Council criticized the word "spastics" as a description of sufferers from cerebral palsy.

The Society of Medical Officers of Health invited the Council to nominate a few general practitioner members to continue a discussion with representative members of the Society on the future relation between the public health service and the general practitioner in regard to the care of children from birth to school-leaving age under the new National Health Service scheme. The Council accepted the invitation and appointed for this purpose Dr. F. Gray, Dr. J. A. Pridham, Dr. H. H. G. Sutherland, and Dr. J. G. Thwaites.

The Council accepted a recommendation of the Dominions Committee that a special committee be appointed to consider and report on the question of contact with and co-operation between the profession in the Dominions and in this country, and between the Dominions themselves. The choice of personnel of the committee was left to the next meeting.

Mr. Lawrence Abel was appointed to represent the Association at a conference to be called by the British Standards Institution at the request of the British Hospitals Association on the question of forming an advisory committee to recommend the preparation of British standards for articles of hospital equipment in common use.

The Secretary read a letter from the Food Rationing (Special Diets) Committee of the Medical Research Council in reply to the protest which the B.M.A. Council had made at its last meeting concerning the statement of the Committee that the medical profession was not maintaining a high standard of accuracy in its priority milk certification. The letter, which recalled the history and constitution of the committee and stated that its functions were purely advisory, was described by the chairman as not a very useful communication, but he said that there was no need to carry the controversy further, and it was to be hoped that the points made by the Council had gone home and that there would be no repetition of such statements.

It was announced that an invitation had been received from the Cambridge and Huntingdon Branch to hold the Annual Meeting of the Association at Cambridge in 1948. It was recalled that the first provincial meeting held after the 1914-18 war was at Cambridge in 1920 and was highly successful. The Branch was thanked for its invitation, which was accepted, subject to agreement concerning the date, to be considered at the next meeting of Council.

The Council concluded its business at 6 p.m.

TUBERCULOSIS ALLOWANCES

A circular from the Ministry of Health on tuberculosis allowances for dependent children authorizes increased rates as follows: for dependants aged 11 and under 16, 10s. 6d.; aged 5 and under 11, 9s.; aged under 5, 7s. 6d. The new scale applies from Dec. 16, 1946, and replaces that set out in para. 42 of Memorandum 266T so far as it relates to dependants under 16.

PAYMENT OF VISITING STAFFS OF VOLUNTARY HOSPITALS

THE GRIMSBY SCHEME

As was reported in the Proceedings of Council published in the *Supplement* of Nov. 23, the Council decided on Nov. 6 to recommend that, without prejudice to future arrangements under the National Health Service, the visiting specialist staffs of voluntary hospitals should during the interim period be paid salaries assessed on the basis of five guineas for a session of two hours. Before this decision was taken a carefully worked out scheme of payment had already been produced by the chairman of the Medical Staff Committee of the Grimsby and District General Hospital and had been approved by both the Medical Staff Committee and the Management Committee. Details of the scheme will be of interest to other hospitals which are considering the same problem.

The basis of the Grimsby scheme is the five guineas rate of payment for a session of approximately two hours, but for various reasons a rigid application of this method was considered impracticable. It would have resulted, for example, in disparities between the amounts received by different individuals, which in the special local circumstances were thought to be excessive. The scheme eventually adopted, and accepted as equitable by all concerned, is shown in the following table.

No. of Sessions	Payment per Session	Annual Salary
1½	1 at 5 guineas	£355
2	" 3 "	£436
3	" 5 "	£709
4	" 5 "	£872
6	" 5 "	£1,193

The approximate number of sessions each week which the various members of the staff consider necessary for the efficient performance of the work in their departments have been ascertained. They vary as shown above, and payment has been arranged provisionally on this basis. It has been agreed that each member of the staff will submit a monthly record of sessions actually undertaken to the chairman of the Medical Staff Committee, who at the end of three months will negotiate with the Management Committee any alterations in the provisional scheme which may prove to be necessary.

The sessional remuneration will cover out-patient clinics, theatre lists, ward rounds, and any other services rendered by the visiting staff, time spent on pay-bed cases (including operations on private cases) being excluded. The staff have agreed to forgo any remuneration for attending the hospital for emergency work and any charge for expenses of travel to the hospital. It has been agreed also that all moneys directed to the medical staff fund for allocation to the visiting staff will be absorbed in the general staff fund, as the staff will now be paid from the general funds of the hospital.

The tenure of office of the visiting staff will not be affected in any way by this new scheme, the adoption of which is without prejudice to future arrangements under a national health service.

RECRUITMENT OF SPECIALISTS

An Appeal for Women Volunteers

The Minister of Health has transmitted to the Central Medical War Committee a recommendation of the Medical Priority Committee, with which he is in full agreement, that the possibility of obtaining volunteer women specialists in certain categories for service in the Forces should be explored.

There is at present a need for gynaecologists for work among the families of Service men overseas, particularly in the B.A.O.R. Both the Army and the Royal Air Force can employ women qualified in this specialty, and also women anaesthetists, pathologists, and radiologists. The Central Medical War Committee is experiencing great difficulty in securing a sufficient number of male specialist recruits to meet the requirements of the Services and accelerate the release

of specialist officers at present serving, whose demobilization is lagging far behind that of medical officers generally. The Committee appeals for women volunteers, not above the age of 40, in the four specialist categories mentioned above. The period of service for recruits joining the Forces in 1947 will be two years, except that volunteer specialists above the age of 30 may, if they so wish, be required to serve for 18 months only. Offers of service should be addressed to the Secretary of the Committee at B.M.A. House, Tavistock Square, W.C.1, or, in Scotland, to the Secretary of the Scottish Central Medical War Committee at 7, Drumsheugh Gardens, Edinburgh.

THE NATIONAL HEALTH SERVICE ACT AND THE NON-TEACHING VOLUNTARY HOSPITALS

The letter printed below has been addressed to the Secretary of the Negotiating Committee by the Association of the Honorary Staffs of the Major (Non-Undergraduate Teaching) Voluntary Hospitals of England and Wales.

45, Lincoln's Inn Fields,
London, W.C.2.
Dec. 9, 1946

DEAR DR. HILL,

With reference to the referendum of the medical profession which is now being taken as to whether we should negotiate with the Minister on the regulations to be issued under the National Health Service Act, I am writing to inform you that the Council of this Association has reaffirmed the following resolution which has already been endorsed by the great majority of the honorary staffs of our constituent hospitals:

"That on matters affecting the principles of the medical profession as a whole the closest liaison and unity of action shall be maintained with the British Medical Association."

We shall be happy if you will give as much publicity to this in the medical and lay press as you think fit.

Yours sincerely,
(Sgd.) H. J. MCCURRICH,
President.

Correspondence

Assistants under the Act

SIR,—“Ex-Service Assistant” (Nov. 30, p. 142) voices a question which is troubling many demobilized medical officers to-day, a question which is not even remotely referred to in the Act. May I urge that the Minister be asked to elucidate this point as soon as possible?—I am, etc.,

London, S.W.7.

JOHN H. SWAN.

SIR,—There is one aspect of the new medical Act to which I would like to call attention. At present I am an assistant doctor. The situation of assistant doctors, often to some extent at the mercy of their chiefs, is not always an enviable one—not necessarily through any fault of the chiefs or of the assistant—but at present the assistant can almost always, unless he is unfortunate, look forward to buying a practice in a few years. In my own case I would have amassed the necessary funds in a year or two. But under the Act assistant doctors are to have no status whatsoever, and their plight will be more unfortunate than at present in that in a few years they will not necessarily have the prospect of becoming practitioners and having their status altered.

In the Act it is stated: “Only medical practitioners who are engaged in medical practice, otherwise than as paid assistants, are of right to provide general medical services under the Act.” No provision whatever is made for assistants such as myself, who in a few years were looking forward to being in full practice. Surely something could have been said in the Act about promotion in a few years for the man in service as assistant at the present time?—I am, etc.,

ASSISTANT DOCTOR

Staffing of Hospitals

SIR,—At a recent Rotary luncheon the speaker was a member of a teaching hospital staff. Towards the close of his talk he explained to the lay audience why the National Health Service Bill proposed differentiation between teaching and other hospitals. I understood there were two main headings: (1) That the additional facilities available enabled diagnosis of patients to be made with greater accuracy. (2) That in the appointment of medical staff the widest choice was available, so that those chosen were on a higher plane than the staff of other hospitals. If this be the general attitude of the staff of teaching hospitals, it is clear that the different treatment to be accorded to them will encourage a split among consultants when dealing with the Ministry, and, further, these reasons are tantamount to saying that if anyone is ill then only by going to a teaching hospital will he receive the best treatment. I was called upon to thank the speaker for his address, and in so doing was compelled to criticize this attitude of superiority, pointing out that selection of staff to fill vacancies only occurred at irregular intervals and that many first-class consultants were serving on the staffs of other hospitals. The staffs of teaching hospitals may seem to be placed in a privileged position under the Act, but this type of argument for lay audiences is grossly unfair to their colleagues on the staff of other hospitals.—I am, etc.,

London, S.E.10.

W. SMITH.

Association Notices

SPECIAL REPRESENTATIVE MEETING

Notice is hereby given that on the requisition of the Council a Special Representative Meeting of the British Medical Association will be held in the Great Hall, B.M.A. House, London, W.C.1, on Tuesday, Jan. 28, 1947, at 10 a.m. The business of the meeting is to consider the results of the plebiscite on the National Health Service Act and the following recommendation of the Council:

"Resolved: That the Negotiating Committee be advised that in view of the results of the plebiscite the Minister be informed that because of the divergence between the principles of the profession and the provisions of the National Health Service Act, the Committee is unable to enter into discussions with the Minister on the Regulations to be made under that Act."

By order of the Chairman of the
Representative Body,

CHARLES HILL,
Secretary.

B.M.A. House,
Tavistock Square,
London, W.C.1.
Dec. 12, 1946.

GROUP OF NON-PROFESSORIAL MEDICAL TEACHERS, LABORATORY AND RESEARCH WORKERS

A meeting of the Group of Non-Professorial Medical Teachers, Laboratory and Research Workers, to which all members of the Group are invited, will be held at B.M.A. House on Thursday Jan. 2, 1947, at 2 p.m.

Members of the Group are invited to forward to the Secretary, B.M.A. House, Tavistock Square, London, W.C.1, suggestions or recommendations for consideration by the meeting.

(Sgd.) CHARLES HILL,
Secretary.

Sir Charles Hastings Clinical Prize

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of fifty guineas, is again open for competition. The following are the regulations governing the award.

1. The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice: it includes a money award of the value of fifty guineas.

2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3. The work submitted must include personal observations and experiences collected by the candidate in general practice, and high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, the interpretations, and their conclusions.

4. Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1946. The prize will be awarded at the Annual General Meeting of the Association to be held in 1947.

5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.

6. If any question arises in reference to the eligibility of a candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.

7. Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto, and enclosing the candidate's name and address.

8. The writer of the essay to whom the prize is awarded may, at the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.

9. Inquiries relative to the prize should be addressed to the Secretary.

Meetings of Branches and Divisions

COVENTRY DIVISION

An extraordinary meeting of the Division was held in the gymnasium of the Coventry and Warwickshire Hospital on Nov. 2. All practitioners in the district were invited and more than eight attended.

An address on the plebiscite was given by Dr. S. A. Brown, of Birmingham. He explained the implications of an affirmative and negative vote. It was decided that no vote of members present should be taken as it was considered that the completion of the voting paper must be an individual and uncoerced effort of each doctor.

SUNDERLAND DIVISION

The annual address to the Sunderland Division was given by S. Stanford Cade at the Royal Infirmary, Sunderland, on Nov. 2. The lecture, "Present-day Therapy in Malignant Disease," which was illustrated by lantern slides, was of very great interest. In the evening the annual dinner was held and was well attended by members. The guests of the Division included the Marquess of Londonderry, Sir Stanford Cade, Mr. Weldon Watts (member of the B.M.A. Council), and the Mayor of Sunderland. As a reflection of the serious situation in which the profession now finds itself speeches stressed the need for opposition to any loss of professional freedom.

APPOINTMENTS

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.—Physician, Out-patients, G. H. NEWNS, M.D., M.R.C.P., Surgeon, G. H. MACNAB, F.R.C.S., Plastic Surgeon, D. N. MATTHEWS, M.D., M.Ch., F.R.C.S., Surgeon to Ear, Nose, and Throat Department, H. S. SHARP, F.R.C.S.

QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford, E.—Honorary Assistant Surgeon, J. THOMPSON FAIRB, M.S., F.R.C.S., Honorary Anaesthetist, T. MARY WYNTER, M.D., D.A., F. H. BLACKBURN, M.B., B.S., D.A., F. C. EIDERIDGE, B.M., B.Ch., D.A., I. G. BRADDON, M.R.C.S., L.R.C.P., D.A., M. GARDEN, M.R.C.S., L.R.C.P., D.A.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

GIBBS.—On Oct. 12, 1946, at Mackenzie, British Guiana, to Juanita (née Bozer), wife of Dr. Donald S. Gibbs, a son—Robin Christopher.

THORNEY.—On Dec. 10, 1946, at St. Mary's High Street, Manchester, to Madge M. (née Gillatt) and Roland Thorney, 44, New Hall Lane, Bolton, a son.

FITCHAM.—On Dec. 10, 1946, at Sunderland, to Marjorie (née Furre), wife of Dr. Thubron, a son.

WARD-MCQUAID.—On Dec. 2, 1946, at Animan, Transjordan, to Betty (née Conway), wife of Major Neil Ward-McQuaid, R.A.M.C., a daughter.

DEATHS

NEILGAN.—On Dec. 8, 1946, suddenly, at the Queen Elizabeth Hospital, Birmingham, Dr. A. R. Neilgan, M.D. (Lond.), of 9, Corbett Avenue, Droitwich.

TUBERCULOSIS IN INDUSTRY*

BY

FREDERICK HEAF, M.D., F.R.C.P.

Tuberculosis is a disease full of uncertainties. Our inability to determine accurately the degree of disablement, the possibility of infection in those who have apparently recovered, and the uncertain prognosis of any case cause endless problems to those studying its relation to industry. To the employer, responsible for the welfare of his staff, who has to measure efficiency in terms of costings and production, infection and reduced working capacity are two features of the disease that cause him to look upon the employment of the tuberculous with anxiety. On the other hand there is a natural desire to assist such disabled persons to obtain suitable work with a living wage; we do not wish to penalize anybody because he has tuberculosis.

Much harm can be caused by exaggerating the infectivity of the disease and the relationship to tuberculosis of the fumes and dusts of certain industries. An occupation itself rarely causes tuberculosis, though it may be a predisposing factor; but before we can come to any conclusion we must refer to the present knowledge of the pathogenesis of tuberculosis.

Pathogenesis of Tuberculosis

The majority of persons over the age of 30 have received and recovered from their primary contact with the tubercle bacillus; but the age when the primary infection is received is rising. This is seen from the recent work on skin-testing certain classes (Table I).

TABLE I.—Percentage of Negative Skin Reactors

Authority	Class	No.	Ages	Percentage Negative
Daniels (1944)	Nurses	3,764	All	19.2
Jess (1943)	Nurses	73,000	School	20.4
Jess (1943)	Students		15-19	78.2
Anderson (1943)	Nurses		20-24	76.4
			25-29	51.2
			30-34	30.2
			35-39	17.2
Profit Survey (1944)	Naval boys		15-16	40.0
	London boys		15-16	12.0
	Nurses (voluntary hospital)		16-30	11.5
	Nurses (municipal hospital)		16-30	17.8
	Medical students		Male	16.3
			Female	11.2

The healed primary complex, consisting of the focus at the site of infection and the lymphatic gland into which it drains, appears to confer a certain degree of immunity but at the same time may harbour virulent organisms which, if resistance is lowered, may cause reactivation of the lesion and, eventually, lesions of the reinfection type in other parts of the lung. Whether an exogenous reinfection causes an endogenous exacerbation or is itself the cause of the lesion does not concern us; but in all those occupations in which there is no reason to suppose that the individual is exposed to recurrent infection the chief cause of the development of a secondary lesion is lowered resistance. Where resistance is maintained at a high level by adequate nourishment, rest, and good environment, as in sanatoria or village settlements, constant contact

with highly infectious cases fails to produce active tuberculosis in the large majority of the staff.

Incidence and Mortality

Not only is primary contact with the bacillus occurring later, but the age group showing the highest incidence of tuberculosis is also rising, particularly in males. In Figs. 1 and 2 the distribution of fatal cases according to age groups is shown for the years 1937-9 and 1940-1 for the county of Middlesex, for males and females (E. Lewis-Fanning, 1943). The increase in the higher age groups for males is clearly indicated.

Furthermore, when we work out (Parliamentary report, 1943) the percentage increase or decrease of the 1942 tuberculosis figures compared with those of 1938 for the various age groups the increase in all ages over 10 becomes apparent (Fig. 3).

FIG. 1.—Pulmonary tuberculosis. Males. Distribution of fatal cases according to age groups. (*British Medical Journal*, 1943, 2, 684.)

FIG. 2.—Pulmonary tuberculosis. Females. Distribution of fatal cases according to age groups. (*British Medical Journal*, 1943, 2, 684.)

This means that active tuberculosis is being found more often than before in the more experienced worker. Most of those lesions in the 35-45 age group are probably due to endogenous reinfection resulting from lowered resistance. In women the maximum incidence is earlier and other factors influence the problem. We know very little of the effect that endocrine disturbances have on the development of tuberculosis, and it may be that the unstable state of adolescent girls is related to the rapid rise of the incidence curve between the ages of 15 and 25. But this will not explain the distinct rise in incidence and mortality in the 20-30 age group during the war years 1940-2. The problem we have to solve is how far industry is responsible for the changes in the incidence of tuberculosis in the various age groups.

The rate of discovery of cases has increased, so the rise in incidence is not a true rise in the rate of development of the disease. Some consider

* Read at the meeting of the Tuberculosis Association at Oxford on July 18, 1946.

that the increase in case-finding, mainly by radiography, accounts for 50% of the rise. For the remaining 50% we must look elsewhere. Diet, overwork, anxiety, overcrowding, and poor ventilation are probably the chief predisposing causes.

Influence of Industrial Conditions

Although normally only eight hours of the day are spent in work, it is important that working conditions should be satisfactory, and I am not going to expatiate on the necessity for adequate ventilation, good lighting, and sufficient nourishment during working hours. Absence of these will cause a lowered resistance, which may lead to reactivation of an old focus or to a new focus from recurrent infection from a probably unknown carrier. In workers previously uninfected a progressive primary lesion may develop from the initial infection, or the reinfection may follow so quickly upon the primary that a secondary lesion develops before the primary has had time to heal or acquired immunity to develop. Where working conditions are poor there is often an abnormal amount of dust,

FIG. 3. Percentage increase or decrease of notifications of tuberculosis in age groups in 1942 compared with 1938.

and although it is difficult to demonstrate tubercle bacilli in dust even when collected from rooms occupied by open infectious cases, the incidence of phthisis is usually higher in dusty occupations than in others. Some dusts bear a special relationship to the development of tuberculosis; these dangerous trades are well known, and skiagraphic examination of all entrants is essential, as well as an annual survey of all employees.

It is not easy to estimate the danger of dust to health. The so-called harmless dusts may indirectly spread tuberculosis by causing chronic catarrh in an individual with an undiscovered active lesion. Some time ago I made an investigation of a group of offices where a number of cases of pulmonary tuberculosis had occurred. Sickness due to catarrhal influenzal colds was highest in those offices in which methods of removing dust were most inadequate, and although I could not trace any direct relationship between the incidence of tuberculosis and the degree of dustiness in the offices, the standard of general health in the cleaner offices was certainly higher than in the dusty ones. If the general health was better, then so was the resistance to disease, and there would be less likelihood of tuberculosis developing.

Certain dusts have a direct bearing on the incidence of tuberculosis. For instance, among the grinders of Sheffield the death-rate from respiratory tuberculosis in 1938 was reported in Parliament (1938) to be four times the rate for all persons over 15 in Sheffield. Further evidence comes from the figures of the Silicosis Medical Board (Sutherland, 1940) for the period 1932-9. Of 1,397 deaths due to silicosis, active tuberculosis was present in 797 cases. Numerous reports have shown that

dormant tuberculosis lesions may become active when a simple silicosis has developed. As for the infectivity of dusts in general, complete proof is not usually possible, but Cruickshank (1940), Mitman (1945), and W. F. Wells in America have shown that droplet infection is important in the spread of disease. Coughing and sneezing are particularly mentioned as expelling infected droplets into the air. Dust, by increasing catarrh, may make coughing and sneezing more frequent and so favour the spread of infection.

The importance of working conditions is seen when we consider how the mortality of tuberculosis varies in different occupations (Tables II and III).

TABLE II.—Deaths Registered 1930-2 per 100 Calculated Standard Deaths at Ages 20-65

Occupation, Males	All Causes	Resp. Tuberculosis
<i>Non-dusty Occupations</i>		
Stevedores	121	239
Barmen	149	212
Costermongers	140	200
Dockers	137	186
Waiters	134	176

General labourers	127	146
Printers	89	128
Brewers	121	120
Compositors	92	116
Bargemen	121	110
Typists	77	105
<i>Dusty Occupations</i>		
Grinders	240	757
Sand blasters	304	750
Sandstone masons	180	396
Textile warehousemen	234	364
Metal grinders	137	275
Filers	154	260
Kiln and oven men	157	227
Barbers	122	162
Chimney sweeps	136	150
French polishers	110	148
Coat hangers	113	141
Cobblers	98	131
Horse drivers	126	124
Metal moulders	112	112
Plasterers	112	110
Sawyers	92	108
Bakers	78	71

TABLE III.—Deaths Registered 1931-2 per 100 Calculated Standard Deaths

Occupation, Single Women	All Causes		Resp. Tuberculosis	
	20-65	35-65	20-65	35-65
Nuns	110	110	194	256
Tailoresses	95	96	113	136
Charwomen	126	132	94	126
Dressmakers	108	110	124	119
Waitresses	109	111	124	—
Laundry workers	105	103	151	107
Domestics	106	115	84	103
Weavers	103	118	79	86
Typists	68	69	78	84
Sick nurses	78	74	82	81

Light work under bad conditions can be more harmful than heavy work under good conditions, as is seen by comparing the figures for farm labourers, stone quarriers, smiths, and steel forgers with those of hairdressers, barmen, costermongers and waiters. Heavy work and poor economic conditions are a serious combination—e.g., dockers. With regard to irritant fumes, there is evidence that the inflammatory reaction of the lung to chemical irritants favours the development of tuberculosis. An exception is fumes containing silica. This is supported by the American figures (1919) of 70,552 soldiers gassed in the 1914-18 war, of whom only 173 cases subsequently developed tuberculosis—2.45 per 1,000. The general rate for U.S. soldiers was 3.50 in 1918 and 4.30 in 1919.

Figs. 4, 5, and 6 (compiled from Registrar-General's Returns: 1931-2) show the percentage mortality from tuberculosis of all occupied males in certain industries in relation to various age groups. The mortality is generally higher in the dusty trades: the peak of the curve falling in the 50-55 age group in these and in the 40-45 age group in the non-dusty and heavy occupations. When similar figures are plotted for the Registrar-General's social class divisions (Fig. 7), in all the occupational classes the peak of mortality falls in the 40-45 age group for

males. It would seem that one factor which shifts the tuberculosis mortality to higher age groups is working in a dusty occupation, and that in such work there is a greater risk of dying from tuberculosis over the age of 45 than in the non-dusty occupations.

FIG. 4.—Non-dusty occupations. Males. 1931-2.

clinical significance cause difficulty, and will continue to do so until we have a more accurate method of assessing the degree of activity. At present it is by trial and error that we determine a man's capacity for work, and the allocation of a person with a stationary minimal lesion to modified work, change of occu-

FIG. 6.—Heavy industries. 1931-2.

FIG. 5.—Dusty occupations. Males. 1931-2.

Mass Radiography

With primary infection tending to occur in the higher ages the need for discovering active cases becomes increasingly important, and with the development of miniature radiography, better termed fluorography, many unsuspected active cases have been found. In mass radiography surveys the number of cases found positive by smear examination of sputum is approximately 3.5 per 1,000 examined. These need sanatorium treatment, and the

pation, or continuance in his present employment is largely a matter of guesswork.

Curious situations may develop as a result of mass radiography. When the person in whom an active and possibly infectious lesion is discovered refuses to accept advice, the authorities are in a difficult position: the information, being confidential, must not be divulged to the managers of the firm

FIG. 7.—Social classes. Males. 1931-2.

concerned. Occasionally an error of judgment may have been made by the medical staff of the mass radiography unit, and as a result of an abnormal film being pronounced normal the management may retain the man at work, with a considerable occupational risk. Should that worker develop the disease the management might claim justification for their action because of the normal report.

The position of the industrial medical officer is somewhat

in the works in whom abnormalities have been discovered but must not be given the names of the persons who have tuberculous lesions. A much closer link between the tuberculosis dispensary, the local labour office, and the welfare unit of the firm is required; and a workers' health and welfare committee should be formed where these matters can be discussed without prejudice. In this way suitable employment for a disabled tuberculous person might be arranged in the works without raising criticism. The importance of strengthening the links between the D.R.O., the tuberculosis officer, and the local labour office of the Ministry of Labour is recognized in the Ministry of Health Circular Letter 52/46, May 15, 1946, which states that in future the T.O. must inform the L.O. of every tuberculous person under his care who in his opinion is fit for a measure of employment and needs and desires assistance in finding it, and any patient who may not be fit for employment but nevertheless wishes to have advice about employment prospects, registration, and the facilities of the Disabled Persons Employment Act (1944). The T.O. must also furnish, at the request of the D.R.O., medical reports on Form D.P.1(X), and provide facilities for him to visit patients at the dispensary and advise him as to the nature and conditions of work suitable for the particular patient concerned. This is not easy, and much research is needed into the problem of employing the disabled.

There are other situations in mass radiography surveys causing some apprehension—e.g., searching for tubercle bacilli in symptomless cases showing minimal pulmonary shadows. Laryngeal swabs and gastric lavage are producing a high percentage of positive results in these otherwise apparently healthy people. Webster (1943), in his examination of 1,630 cases, discovered by mass radiography among Australian military forces 364 positive cases of whom 189 said they were perfectly well and symptomless after exhaustive investigation. Are we to regard them as active, infectious cases with respect to their employment and need for treatment? Our laboratories must be above suspicion, as serious errors can occur from unsound methods or technique. Personally I think we should take every precaution to prevent the spread of infection and to arrest the disease, for we have a good chance of curing these cases; and that a compromise between employment and treatment while activity exists should be avoided. In the past too much time and skill have been wasted on the impossible task of restoring the advanced case to health when consideration of the morbid anatomy would have caused us to direct our energies to efficient treatment of early cases. Mass radiography is increasing our opportunities to effect permanent cures, and we must not default by relying on the apparently healthy condition of the individual, making a wrong assessment of his capacity for work because we can offer him a light job.

Mass radiography can be of great value in discovering any person with clinically significant shadows in the chest skiagram and eliminating him from occupations in which the risk of developing tuberculosis is high. As mass radiography of the whole population is impracticable, it is best applied to serial examination of those sections of the community in which the tuberculosis risk is highest. Pre-employment radiographic examinations throw a serious responsibility upon employers in hazardous industries, for if tuberculosis subsequently develops in an individual it can be more conclusively attributed to conditions of employment.

Rehabilitation

Great advances are being made in the rehabilitation of the tuberculous by granting financial assistance. Memorandum 266T. of the Ministry of Health provides for financial assistance to pulmonary cases likely to return to work. It is insufficient for his needs, but the principle is right. It is a wartime emergency measure and will probably be abolished when the National Insurance Bill is passed. The industrial section of this Bill is of particular interest as regards tuberculosis. Part iv, clause 54, 2a, states:

"A disease or injury may be prescribed (for the purposes of this part of the Act) in relation to any insured persons, if the Minister is satisfied that (a) it ought to be treated, having regard to its causes and incidence and any other relevant considerations, as a risk of their occupations and not as a risk common to all persons,

and (b) it is such that, in the absence of special circumstances, the attribution of particular cases to the nature of the employment can be established or presumed with reasonable certainty."

Perhaps the Minister will schedule tuberculosis as an industrial disease, but this is doubtful, and it is probable that every claim will be taken on its merits. As the injury benefit is 19s. per week more than the sickness benefit there will be more claims that tuberculosis shall be considered as an injury. There has already been one ruling in court that a tuberculous lesion is an injury in the meaning of the Act. Our incomplete knowledge of the pathogenesis of tuberculosis will increasingly emphasize the need for a national tuberculosis research body supported by Government funds to investigate tuberculosis problems—particularly the development of the disease and assessing the activity of the lesion. The best solution for the tuberculous would be to enhance the privileges under Memorandum 266T. in favour of all those suffering from tuberculosis and thereby eliminate the need for proving that the disease is due to the nature of the employment.

Disabled Persons Employment Act

The Disabled Persons Employment Act, 1944, is another measure which provides means whereby the tuberculous may be rehabilitated. The full benefits of this Act have not yet been appreciated, as some time must elapse before the machinery for its working is complete, but the Minister of Labour has powers to establish a full rehabilitation scheme. One drawback to the smooth working of the Act is the reluctance of tuberculous persons to put their names on the Disabled Persons Register. The disabled person hides as much as possible his having suffered from the disease for fear of being penalized.

The general opinion of employers is against the inclusion of tuberculous persons in normal industry. Bashford and Scott (1936), after examining the histories of 3,755 cases of pulmonary tuberculosis occurring in a Post Office staff of 185,000 men and 55,000 women, concluded that of those who incur tuberculosis not more than 50% return to work even after prolonged treatment; and that of those who returned to industry there was a further wastage of about 48% from recurrent pulmonary tuberculosis or other forms of ill-health by the end of ten years. The heaviest wastage occurred in the first six years. There was a further wastage of 14% of those who survived the first ten years.

The time has come to treat this problem realistically. Two most important principles are that the employment of the tuberculous in industry must not disturb the relationship between management and labour by introducing special privileges and conditions for a selected few employees, and that the tuberculous person may be employed at work which requires a low energy output, but while he works he must complete his duties, and not expect that he can slack because he is tuberculous.

Employable patients who have received the maximum benefit from treatment are in two groups: (1) sputum-positive; (2) sputum-negative. (1) These are infectious, have an active focus in the lungs, and are particularly liable to relapse if subjected to strain or anxiety. Only exceptionally should they be re-employed in normal industry. They need special workshops and close medical supervision. These can be provided under the Disabled Persons Employment Act. They present a formidable problem. A subsidy is needed to cover their reduced capacity for work, and workshops in the form of industrial clinics where sheltered conditions can be provided. (2) These can be subdivided into three classes: (a) fit to resume on full time their occupation or trade; (b) fit to resume work on part time; (c) cannot resume their occupation or trade but could be employed at other work if properly trained. The first class does not present any difficulty. The second can sometimes be accommodated by large firms, but difficulties over wages and privileges are too great for the small firm. So-called light work often means dead-end jobs with poor pay. Unless there is a prospect of return to full work within twelve to eighteen months it is better for them to be retrained in work within their capacity and skill. It is highly important that the energy output required is within the man's capacity. The research of Orr and Leitch (1938) on the calories expended per hour (Table IV) in carrying out certain tasks should

form a standard by which we can gauge the suitability of any occupation for a particular individual. However, we still seek an easy means of determining the limit of energy output for tuberculous patients beyond which it is unsafe to go. When this is known it will not be difficult to suggest suitable occupations for most patients when sanatorium treatment is completed.

TABLE IV.—*Calorie Requirements of Man (Orr and Leitch)*

Occupation	Calories per Hour
Sewing	10-20
Writing	10-20
Sweeping	110
Stone mason	350
Sawing wood	420
Tailoring	50
Typewriting	55
Bookbinding	65
Ironmaking	90
Painter	160
Smith (heavy)	350
Coal-mining	320
Walking	150-240
Charwomen	81-157
Securing	73
Seamstress	6
Dusting	110
Carpentry	155

Those who cannot be re-employed in their previous occupation will have to be given other work, though to maintain the original standard of living is often difficult. Retraining usually means either temporarily or permanently lower wages for the person over thirty. The peak of the tuberculosis-incidence curve in males is shifting to the higher age groups, so this problem is likely to increase. The situation calls for the establishing of centres for the tuberculous similar to Egham, with close connexion with special workshops where continued employment may be obtained for those unable to find suitable posts in normal industry. Considerable advance in the principles underlying the employment of the tuberculous has been made by the Ministry of Labour's agreeing that such persons need not be given outdoor work. Most outdoor jobs are heavy and often poorly paid. It is very satisfactory that this should be recognized and that sedentary work should be arranged.

Russia has successfully linked sanatorium treatment with the prophylactic workshop attached to the main works, which provides modified employment for patients still under treatment at a dispensary or a night sanatorium. Adequate nourishment and rest are ensured, but remuneration is on a lower scale than that of the healthy worker. The scheme is worthy of close study and might be adopted with slight modification here.

Conclusions

To summarize the relationship of industry to tuberculosis: occupation rarely causes tuberculosis, but conditions of labour can predispose to it. These conditions, particularly the elimination of dust, which appears to be more harmful with regard to tuberculosis in the higher age groups, should receive continued attention, and also that all workers should obtain adequate nourishment during work hours. Tuberculous persons entering hazardous employment should be examined periodically by miniature radiography. A fundamental principle is the exclusion of infectious persons from normal industry, except where the other workers can be protected and suitable employment provided for the disabled person. Pre-employment radiography imposes a liability on the employer when engaging proved healthy persons in a hazardous industry. The return of the tuberculous person to normal industry must be through a properly organized rehabilitation scheme, which should be closely associated with industries that can provide suitable employment for recovered persons. Recent legislation has made this possible, but the co-operation of industry as a whole is needed to ensure success.

A national tuberculosis research organization would investigate methods for assessing the disability of those who are recovering or have recovered from the disease. The Government has accepted its share of the liability; it is now our responsibility to take advantage of the privileges provided and develop this section of industrial medicine. Special workshops or industrial clinics are required for those who cannot take their place in normal industry; indoor work within the disabled

person's capacity is more suitable than outdoor, which is usually heavy and poorly paid.

THE INTERNAL COMBUSTION ENGINE AND THE SPREAD OF DISEASE

BY

G. M. FINDLAY, C.B.E., M.D., D.Sc., M.R.C.P.
 Late Consulting Physician, West African Command

From the dawn of history infectious diseases, together with other specialized merchandise, have spread along the trade routes of the world, whatever the mode and speed of transport. To-day it is the speed of travel both on land and in the air which adds danger to the spread of disease from endemic to non-endemic areas. Fifty years ago, when the first European missionaries went to Uganda, it took them between three and four months to walk from Mombasa; to-day the same journey can be made by air in from three to four hours. Flights of twenty-four hours for a journey from West Africa to India or of sixteen hours from England to West Africa are becoming commonplace. With jet-propelled planes the flying times will be even shorter; speeds of 500 to 600 m.p.h. (800-960 km.p.h.) for passenger planes are predicted in the near future. But it is not only in the air that the barriers to rapid intercourse have fallen. A generation ago few Africans dared to wander far from their tribal lands: if they did, it was at the risk of death, or at the best enslavement. Mountains once formed an insuperable barrier. In the old days, for instance, the Nyakysa in East Africa feared to cross the 8,000-ft. (2,438-m.) range which blocks their valley to the north, since they were liable to die from cold. Disease was also a barrier, for the same tribe did not often visit the adjoining Kinga, who live on the Livingstone Mountain, not only because of the cold but because they were afraid of catching tick fever, which was endemic among the Kinga (Wilson and Wilson, 1945). One small tribe in the Nuha Mountains, in south-eastern Kordofan, are said to have introduced tsetse flies in order that the Baggara, or Cattle Arabs, should give them a wide berth. Evans-Pritchard (1940) relates that the Galla and Amhara of the Ethiopian highlands refuse to descend to the plains for any length of time for fear of malaria. Immediately before the war, and still more during the war, motor roads have been built throughout the Tropics in ever-increasing numbers. Shakespeare's prophecy that "the vasty wilds of wide Arabia are as thoroughfares now" is no less true of Africa and Asia, and the local inhabitants have readily taken advantage of those roads and of the motors which pass along them. There is evidence that in the past few years in Africa yellow fever, cerebrospinal fever, relapsing fever, trypanosomiasis, intestinal bilharziasis, and gonorrhoea have all been spread by those who have used the roads in their search for work or trade.

The possibility that infectious diseases and their insect vectors might take advantage of the rapid means of transport now available was translated into fact when in 1930 Shannon discovered *Anopheles gambiae* in the city of Natal, Brazil; it had apparently arrived from tropical Africa, where it is the most important malarial vector, not by air but by one of the fast torpedo-boats employed in connexion with the French transatlantic air service.

In 1933 the first International Sanitary Convention for Aerial Navigation was drawn up; but in many ways it was unworkable, and in 1944 some of its provisions were modified in the light of more recent knowledge. During the war the possibility that infectious diseases or their insect vectors might be carried from endemic to non-endemic areas was met in the more dangerous areas of Africa by the formation of inter-Allied mosquito control boards, the membership of the boards being

made up of civilian officials and Allied Service personnel. With the end of the war these control boards have in most cases lost their Service members, together with many of their executive staff. Although for the moment there is probably a decrease in the number of persons flying, in a short time the world's air routes will once again be crowded with passengers and freight. The present is therefore a suitable time to discuss very briefly how far the present organization is adequate to guard against the spread of disease by air.

Disease and its Spread by Air

The diseases which are specially feared in relation to spread by air traffic are yellow fever and malaria. There are, however, others which might readily be spread by infected persons or by insect vectors—for example, dengue, poliomyelitis, the insect-transmitted encephalitides, and trypanosomiasis, as well as acute respiratory infections such as influenza.

Yellow Fever

Yellow fever may be carried by an infected mosquito or by a person incubating the disease. The endemic yellow fever zones in Africa and South America, shown in the accompanying map (U.N.R.R.A. Health Division, 1945) are now traversed by a number of air routes. In Africa a great part of the continent

between 15° N. and 10° S. is involved, but Tanganyika is excluded. The Barotse Province and the Balovale district of Northern Rhodesia are, however, included, as are the islands in the Gulf of Guinea. The Port of Massawa, in Eritrea, has been excluded.

In South America the ports of Belem in Brazil, Cayenne in French Guiana, Paramaribo in Surinam, Georgetown in British Guiana, the Caribbean ports of Colombia and Venezuela, and the cities of Caracas in Venezuela, Bogotá in Colombia, and Corumbá in Brazil are excluded. In addition, the Ilheus and Itabuna districts in the State of Bahia, Brazil, are for the time being regarded as endemic yellow fever areas.

It will be seen that the portion of the earth where yellow fever is endemic is too large to be absolutely avoided by long-distance aeroplanes, although in the future it may be possible for aeroplanes to fly the 4,000 miles (6,400 km.) from Cairo to the Union of South Africa without touching down inside the yellow fever area.

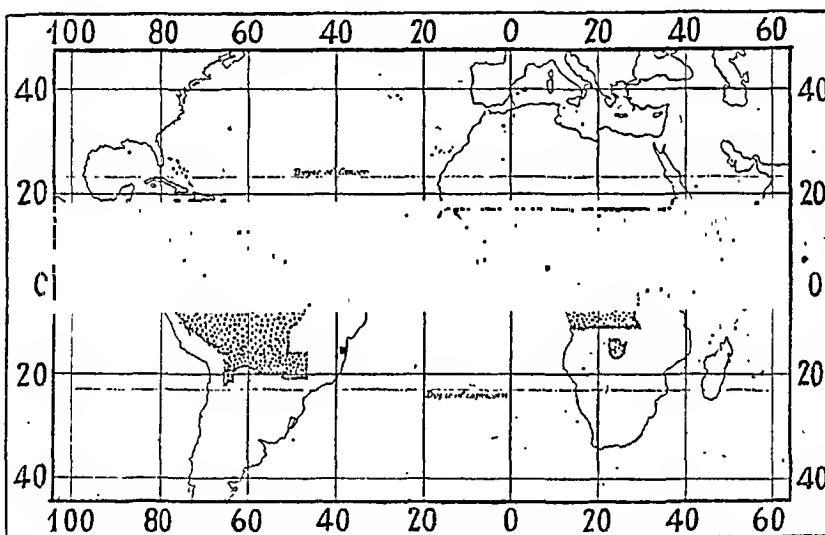

Experiments made before the war by Trolli (1932), Hicks and Chand (1936), and others showed that mosquitoes could quite easily survive long journeys by air of over 9,000 miles (14,400 km.) in which heights of 10,000 to 12,000 ft. (3,048-3,658 m.) were reached. Griffiths (1933) also proved that mosquitoes released in the cabins of aeroplanes do not necessarily leave the aeroplane at intermediate stops on the air route. Before the war a number of mosquitoes from the Old World, capable of transmitting yellow fever, had been found in aeroplanes (Whitfield, 1939), including *Aedes aegypti*, *A. simpsoni*, *A. luteocephalus*, *Taeniorhynchus* (*Mansoniodes*) *africanus*, and *Culex fatigans*.

While the chances of an infected mosquito gaining entrance to an aeroplane may not be great, they are by no means remote. With compulsory yellow fever immunization for all those who fly through endemic zones the chances of an infected person being carried are, however, extremely small, provided that active yellow fever vaccine has been used.

Malaria

Malaria may, also be spread by a person with parasites in his blood or by the carriage of some of its insect vectors. It is now recognized that different strains of the same species of malarial parasite exist, some being more virulent than others. The introduction of highly virulent strains of *falciparum* parasites into an area where *vivax* strains were predominant might or might not be followed by a severe outbreak of malaria; the experiment has not been tried. After the war of 1914-18 a small outbreak occurred in South-East England as a result of the return of infected soldiers, and a similar outbreak has already taken place in the Berlin area. A number of the anopheline vectors of malaria were found in aeroplanes in Africa and in America both before and during the war. The list includes *Anopheles gambiae*, *An. funestus*, *An. pharoensis*, and *An. albimanus*. While the original appearance of *An. gambiae* in the New World was not directly due to aeroplanes, during the war years it did successfully make the Atlantic passage by air. The difficulties in eradicating it from Brazil have been retailed by Soper and Bruce Wilson (1943). There is also some evidence to show that *An. albimanus*, found breeding at Boca Paton, Florida, arrived from South America by air. Of the anopheline vectors of malaria which have travelled by

air, *An. gambiae* is probably the most dangerous in view of its domesticity and its catholic taste in breeding-places. At present it is found throughout Africa south of the Sahara and as far north as Wady Halfa, just south of the frontier between Egypt and the Anglo-Egyptian Sudan (Lewis, 1942-1944). It is probable that it has been at Wady Halfa for many years. It has, so far as is known, never reached the Nile Delta, though during the war it was found in Central Egypt. *An. gambiae* is present in Madagascar and has

The epidemic yellow fever areas of the world as delineated by the expert commission on quarantine, U.N.R.R.A. Health Division.

been identified in the Aden hinterland and at Jeddah, in Arabia.

Other Diseases

Tsetse flies are inveterate travellers by train, motor-car, and even on the back of the humble pedal cyclist. It is therefore not surprising that they should have been found in aeroplanes in Africa (Symes, 1937). During the war on two occasions *Glossina palpalis* were also caught in Natal, Brazil: their only means of crossing the Atlantic must have been by air (Soper and Wilson, 1943). Chaga's disease has not been reported outside the New World.

Other diseases transmitted by mosquitoes are dengue and the various forms of encephalitis at present limited to America and Japan. There was, however, before the war some evidence that Japanese Type B encephalitis had spread into China. Flies are frequent passengers in aeroplanes; they are, it seems, able to carry poliomyelitis and probably infective hepatitis. Strains of poliomyelitis are known to vary in virulence, while it is also possible that there are different strains of infective hepatitis with varying degrees of virulence. The geographical distribution of sandfly fever and kala-azar by no means coincides with that of *Phlebotomus*. Plague transmission is a more remote danger, though during the war a live mouse was found in an aeroplane arriving at Miami, Florida, from San Juan, Porto Rico.

Prevention of Spread of Disease by Aeroplanes

The measures which are necessary to prevent the spread of insect-borne diseases by aeroplanes are of course well known,

and if they are carried out properly should make the risks infinitesimal. These measures are the sanitary control of (a) aerodromes, (b) aeroplanes, and (c) air-passengers, crews, and ground-staff.

The sanitary control of aerodromes requires a considerable staff. For aerodromes dealing with international traffic the areas involved are large: runways 3,500 yards (3.2 km.) long are required, and extensions up to 5,000 yards (4.5 km.) are visualized in the future. The existence of many acres of flat tarmac and of large hangars means that in the Tropics during the wet season a tremendous volume of rain-water often has to be run off the aerodrome area. Clearing of drains and soil erosion have to be guarded against. Mosquito control must be exercised not only over the actual aerodrome but over a zone of country extending in some directions or as much as three miles (4.8 km.), if during tropical storms mosquitoes from uncontrolled areas are not to be blown on to the aerodrome. This involves the spraying of native villages, and in some cases of urban areas, with D.D.T. or other insecticides, as well as the careful supervision of drains, lagoons, and all other possible breeding areas. It is obvious that a large staff is required. During the war many extensive drainage schemes were begun in Africa in order to sanitize aerodromes. Some of these schemes were finished before the end of the war, other were left unfinished. In any case anti-mosquito schemes, cannot look after themselves; constant vigilance is necessary, and the cost of maintenance is usually high.

The sanitary control of aeroplanes involves the use of insecticides. The ideal method is undoubtedly the application of an insecticide to the inner walls of the aeroplane (Madden *et al.*, 1945), combined, while in flight, with some form of aerosol spray containing a rapidly acting insecticide such as pyrethrum (Maekic and Crabtree, 1933). During the war, when the Freon bomb or a hand-spray was the standard equipment, disinsectization was not as a rule carried out until the aeroplane had been grounded, and then often in so perfunctory a manner that insects had ample opportunity either to leave the aeroplane or to remain in it alive for a further journey.

The sanitary control of passengers, crews, and ground-staff involves immunization against yellow fever. In accordance with the International Sanitary Convention for Aerial Navigation of 1933, as modified by the Convention of 1944 (Stock, 1945), all passengers and crew must have been immunized not less than ten days and not more than four years before the date at which they enter the yellow fever endemic zone.

Before the war, when yellow fever immunization was still in an experimental stage, the majority of persons inoculated were tested for immunity. Under wartime conditions this became impossible. Some tests, however, were carried out in West Africa with discouraging results. Thus of 156 British officers and other ranks inoculated within six months in 1943, 83 were protected while 73 were not. There were two reasons for these results: (a) failure to remove residual moisture from the vaccine during the process of preparation, and (b) maltreatment of the vaccine after leaving the place of manufacture. The first difficulty has now been completely overcome, and further tests show that between 97 and 98% are successfully vaccinated. Maltreatment of the vaccine has occurred in a number of ways: breakdown of refrigerating plant used for storage of vaccine; inefficient vacuum flasks for its transportation; the use of hot syringes for injecting the vaccine; and exposure of the redissolved vaccine to high temperatures. The following figures show the results of using an inefficient vacuum flask for transporting yellow fever vaccine (Batch A) some 50 miles (80 km.) by road in West Africa. Tests were made a month after immunization, and all injections were carried out by the same pathologist.

Batch	No. of Persons Protected	No. of Persons Not Protected
A ..	44	21
B ..	17	1
C ..	15	1

Since the yellow fever vaccine is thermolabile it is obvious that considerable care must be exercised in its storage and handling.

Yellow Fever Certification

All passengers by air who are travelling through endemic yellow fever zones must now carry a certificate that they have received yellow fever vaccination more than ten days before the date at which they enter the endemic yellow fever zone and not longer than four years. At present an international yellow fever certificate is printed by the World Health Organization, following U.N.R.R.A., who had issued a booklet, appropriately bound in yellow, containing a yellow fever certificate.

A few minutes' search, however, at an aerodrome allowed seven different types of British yellow fever certificates to be collected, all signed by different medical officers. Since those who examine yellow fever certificates are not always provided with specimens of these various types or with a list of the medical officers who are empowered to sign such certificates, it is not surprising to learn that yellow fever certificates have in the past been forged and that it is reported on credible information that on the Continent there is a black market with a recognized tariff for these certificates. It is therefore obvious that to prevent the forgery only one form of yellow fever certificate should be available, while lists of the medical officers whose signatures are accepted should be kept in every airport.*

The International Sanitary Convention for Aerial Navigation of 1933 as amended by the Convention of 1944 (Stock, 1945) provides for the isolation of persons who do not hold a valid anti-yellow-fever inoculation certificate and who are travelling by air from an endemic yellow fever area to one in which the disease does not exist but in which conditions may permit of its development. Such persons may be isolated in screened quarters until such a certificate becomes valid or until six days shall have elapsed, whichever is the lesser period. The Convention also provides that in exceptional cases the countries signatory to the Convention may issue "certificates of urgency" to persons not immunized against yellow fever "whose unobstructed passage is absolutely and immediately essential on grounds of high policy, certifying that a passage without hindrance to the bearer of the certificate is urgently necessary."

As a wartime emergency such a measure was doubtless essential. In Crown Colonies the right to grant certificates of urgency was vested in the governor, but in practice it involved the granting of these certificates by the governor's deputy, the Colonial Secretary, or his deputy, and in fact by a considerable number of persons in each secretariat. The Governments of the Union of South Africa and of Southern Rhodesia have now very wisely refused to accept these certificates of urgency, the use of which should be everywhere abolished.

During the war, in order to reduce the risk of any person in the incubation period of yellow fever coming within controlled aerodrome areas all ground staff as well as casual labourers were immunized. In some areas this involved the immunization of a considerable proportion of the population of villages and towns in proximity to aerodromes.

Need for an International Organization

The organization which dealt with the sanitary control of aerodromes and aeroplanes during the war has now largely been dispersed, but peace has not brought a solution of these problems, which remain as urgent as ever. Yet many of the countries which find themselves on international air routes have neither the staff nor the money to devote to matters which are not their primary concern. There are three possible solutions. It may be thought that the danger of the spread of infectious diseases and their vectors is negligible and that therefore there is no need to have any special organization to deal with air transport. This point of view, in face of the International Aerial Sanitary Convention of 1933, amended in 1944, can hardly be maintained. It may be thought that there is a danger but that it is safe to allow each separate country to have complete control over the international aerodromes in its own territory. In view of the many loopholes which became apparent during the war, and of the meagre resources possessed by many countries for dealing with international air traffic, it seems that the only really satisfactory organization is an international one with an adequate staff and funds of its own. This concern might well be placed under the World Health Organization of the United Nations, and in close association with P.I.C.A.O. (the Permanent International Civil Aviation Organization). Its functions would be: (1) To take sanitary control of all aerodromes and aerodrome areas which are considered to be involved in the spread of infectious diseases from endemic to non-endemic areas; (2) to control the disinsectization of all aeroplanes on routes where spread of infectious diseases is likely to occur; (3) to control the storage

* The Government of India now insists that valid yellow fever certificates must be signed only by approved persons, and other Governments are adopting the same procedure.

of yellow fever vaccine and its injection under standardized conditions, and to approve institutes for the testing of yellow fever vaccines; (4) to control the issue of yellow fever immunization certificates.

So far as the sanitary control of aerodromes and aerodrome areas is concerned, this implies something more than the biannual meeting of government officials which before the war occurred at the Office International d'Hygiène Publique in Paris. It would involve a partial abrogation of sovereignty on the part of the territories concerned, since the sanitary staff engaged in this work would be responsible not to local directors of medical services but directly to the World Health Organization of the United Nations.

In the age of the internal combustion engine the spread of disease can be held in check only by a scheme which is internationally sponsored and internationally controlled.

ABACTERIAL PYURIA

WITH SPECIAL REFERENCE TO INFECTION BY SPIROCHAETES

BY

WALDEMAR E. COUTTS, M.D.

AND

ROBERTO VARGAS-ZALAZAR, M.D.

(From the Urological Clinic, Medical College, Chile University, South America)

The problem of sterile, amicrobic, or abacterial pyuria is occasionally brought up in medical publications in relation to a new case observed. It is a problem that has interested us for several years, and we have published some papers on the subject in Chilean medical journals (Vargas-Zalazar, 1937; Coutts, 1938; Coutts and Vargas-Zalazar, 1945); our findings, however, may not be generally known. In our opinion "abacterial" is the right designation for this syndrome, which may originate through ascending or descending infection of the urinary tract by viruses, spirochaetes, or protozoa. In most cases causative diagnosis was not made because dark-ground observation of centrifuged urinary deposit of bladder or kidney urine samples has not been incorporated into routine laboratory practice.

We refer later to cases of abacterial pyuria, which according to our findings are produced by spirochaetes. Our first suspicion of the possible action that some of these micro-organisms might have in the production of such a type of pyuria was aroused more than ten years ago.

A medical student consulted us for slight dysuria and cloudy urine, in the absence of urethral discharge, which had been troubling him for a few days. Prof. Bisquertt-Torres, who had charge of the case, found pus cells but no bacteria of any kind in urine obtained direct from the bladder. Cystoscopy revealed only a slight congestion of the trigone. Bilateral kidney-pelvis catheterization performed on two occasions showed numerous pus cells but no bacteria. Cultures and animal inoculations of urine from both kidneys and bladder failed to reveal Koch's bacilli. At the time Bisquertt-Torres and one of us (Coutts) thought that the most probable diagnosis was that of bilateral renal tuberculosis. Before travelling to Switzerland the patient visited his dentist, who removed a gold-filled molar which was somewhat tender on pressure and showed a certain amount of apical damage in a radiograph. Urinary symptoms then sub-

sided rapidly, the urine cleared, and the pus disappeared. He is now a well-known physician, is married, has several children, and enjoys good health.

In 1937 Vargas-Zalazar, at one of the weekly staff meetings of our clinic, presented a case of abacterial pyuria. In the discussion Coutts, remembering the above case and some similar ones presented by Wildbolz at the French Congress of Urology in 1933 and treated successfully with arsenicals, suggested a search for spirochaetes in urinary deposits observed under dark-ground illumination. These micro-organisms might proceed from the oral cavity or intestinal tract. In this case spirochaetes were discovered. On perusing the medical literature we found that Briggs (1935), Cook (1936), and Wildbolz (1937) had treated similar cases of abacterial pyuria successfully with arsenicals.

The following is a summary of five cases of abacterial pyuria in which we were able to demonstrate spirochaetes or spirilla under dark-ground illumination of deposit from centrifuged bladder urine obtained by catheter.

Case Reports

Case 1.—A male student aged 21 consulted Vargas-Zalazar privately in 1937. He had undergone tonsillectomy at 8 years of age. His present illness began in 1934, when, after gonorrhoea complicated by epididymitis, his urine on complete bacteriological recovery remained cloudy and contained pus cells. The attending urologist studied the case from a renal point of view and found abacterial pyuria in both kidneys. Investigations for Koch's bacilli were all negative. As the patient felt no symptoms he abandoned further medical care. In 1937 renewed urological studies by Vargas-Zalazar gave similar results. An intravenous pyelogram revealed a right hydro-uretero-nephrosis. Dark-ground investigation of bladder urine showed the presence of large numbers of spirilla. He was treated with one dose of 0.15 g. and three of 0.3 g. of neosalvarsan, and in twenty days pyuria and spirilla disappeared from the urine. Later controls have proved his cure to be complete (Vargas-Zalazar, 1937).

Case 2.—A merchant aged 47 consulted Coutts in 1937 because for two months a slight urinary diurnal frequency and tenesmus had been troubling him. His urine was cloudy and did not clear, nor did symptoms disappear after two successive courses of protosil album. On examination there was no urethral discharge, the urine was cloudy, and the prostate and genitalia were normal. Bladder urine contained numerous leucocytes and some red cells but no bacteria. Koch's bacilli were not seen. The bladder capacity was 150 ml., and the urethral orifices were normal. On the trigone and right wall several aphthoid lesions were observed. Dark-ground illumination of the bladder urine deposit revealed numerous spirilla. Methylene-blue instillations into the bladder and three injections of a pentavalent arsenical intravenously cured him. When last seen he was in perfect health and his former trouble had not recurred (Coutts and Vargas-Zalazar, 1945).

Case 3.—A woman aged 34 entered our clinic in 1938. Her previous history was of no importance. The present illness began fourteen months before with slowly increasing urinary frequency by day and night. Terminal haematuria was occasionally present. The bladder urine contained pus and cocci, but Koch's bacillus was absent from several samples. The bladder capacity was 40 ml.; there was intense congestion of mucosa with numerous disseminated ecchymotic spots and patches, some covered by exudate. Local treatment was unsuccessful. Dark-ground examination of bladder urine deposit showed numerous spirilla. Arsenic and bismuth combined cured the condition rapidly (Bisquertt-Torres, 1938).

Case 4.—A married hospital nurse aged 32 began in 1940 to have painless haematuria lasting for two days. There was a similar recurrence in December, 1941. As the loss of blood was not stopped by treatment she was admitted to our clinic. Her bladder urine always showed red cells and a few pus cells but no germs. Koch's bacilli were never found. Blood pressure and coagulation tests were normal. Bilateral renal catheterization on two occasions showed blood in both kidney pelves and very slight pyuria but no bacilli. Koch's bacilli were not found. A descending pyelogram proved normal. Dark-ground examination was positive for spirilla (bladder urine). She was treated with pentavalent arsenic by mouth, and haematuria then disappeared. In November, 1944, haematuria reappeared, and spirilla were found in bladder urine. She was cured with stovarsol and was sent to her dentist (Coutts and Vargas-Zalazar, 1945). Up to the time of writing she had relapsed once again.

Case 5.—A physician aged 49 consulted Coutts in 1946 for dysuria and cloudy urine. Five days previously a dead nerve was removed from the canal of an upper median incisor. A few hours later the upper lip started swelling, and twenty-four hours later an abscess of the anterior portion of the gum was drained surgically. Bladder

symptoms started shortly afterwards. There was no urethral discharge; pus was present in the urine, but no bacteria. Under dark-ground illumination a few spirilla were found. He had been taking sulphonamides. Stovarsol was given by mouth; bladder symptoms subsided and pus disappeared from urine.

Discussion

Cases of abacterial pyuria, besides those already quoted, have also been studied by Schaffhauser (1937), Houtappel (1939), Moore (1940, 1943), Cook (1944), Donovan (1945), Peters (1946), etc. Most of them have been cured with arsenicals, but in no case have spirochaetes been proved to be their cause, although they have often been considered as the possible aetiological agent. Peters (1946) brings this problem up again; because of the prompt therapeutic action of neoarsphenamine he believes that the causative organism belongs to the spirochaete group. The spirochaete, he thinks, has escaped identification, probably because of some morphological peculiarity. Except those published by us (Vargas-Zalazar, 1937; Coutts, 1938; Coutts and Vargas-Zalazar, 1945) only one case of pyuria by spirochaetes appears in the medical literature; it was also studied at the clinic here and reported on by Bisquetti-Torres (1938). According to our observations bladder and kidneys may become infected by the ascending or the descending route. Spirochaetal (non-syphilitic) infection of the male and female urethra is not uncommon. Descending infection is usually of the blood-stream type. Spirochaetes have been found in bladder urine in cases of so-called war nephritis (Salomon and Neveu), in trench fever (Nankivell and Sundell), in relapsing fever (Chung), and in Weil's disease. In our opinion the spirochaetes present in our cases might have a buccal or intestinal origin. Pettit (1928) considered the possible buccal nature of spirochaetes discovered by Croveri in stools; Buttiaux (1930) found them in stools of patients suffering from colitis; Docges (1938) found them in gastric glands in 45% of 103 samples of stomachs selected from 3,400 necropsies; Kritchewski and Séguin (1923) found them in cases of retrograde pulpitis; Cavalié and Mandoul (1921) in alveolar-dental expulsive polyarthritis; Gins (1942) in cases of periodontitis; Saenz de la Calzada (1934) describes a case of urinary frequency of dental origin; Ferreira (1939) reports a case of metastatic infection of the prostate from a dental focus; Goldberg (1943) describes prostatitis and arthritis of dental origin.

In all our cases we found spirilla of diverse morphology; some were slender and had only a few spirals, while others were very similar to *Sp. dentium*. We believe they belonged to the buccal flora, but we have no further evidence of this. Treatment with pentavalent arsenicals was always successful. All cases were submitted to dental attention. In order to demonstrate the presence of these fragile micro-organisms we recommend slow and prolonged centrifugation of freshly obtained bladder urine. Before examining the deposit under dark-ground illumination it is advisable to add a drop of normal saline at 37° C. in order to increase the movements of the parasites.

PERIPHERAL NERVE INJURIES RECENT PROGRESS IN TREATMENT

BY

T. B. MOUAT, M.D., Cb.M., F.R.C.S.

The importance of peripheral nerve injuries in modern warfare is shown by the fact that Spurling and Woodhall (1946) estimate that there were 25,000 peripheral nerve injuries in the second world war, and that they formed 10.5% of battle casualties. There are no fewer than 7,000 end-to-end sutures in the U.S. Registry of Peripheral Nerve Injuries, which was established in November, 1944, to follow up these injuries and assess at regular intervals the results of treatment.

While the final results will not be available for some years, the preliminary reports of surgeons in both American and British neurosurgical teams and centres are of great value and convey information which must influence the future treatment of this type of injury. The opinion expressed in the *Report on Peripheral Nerve Injuries* which was published after the first world war (1920), that the results of treatment are largely independent of the interval between wounding and surgical repair, had already been disproved, as regards delayed suture, by the poor quality of the clinical results and the underlying reasons for failure explained by the important experimental work carried out during the last few years. Thus Holmes and Young (1942), Sanders (1942), and other workers showed that the poor results after delayed secondary suture were due to shrinkage of the neurilemma tubes in the peripheral segment, which delayed maturation of the down-growing axonal fibres; and Gutmann and Young (1944) found that with delay there is progressive atrophy in the muscle fibres and end-plates, so that the new fibres returning down the tubes are, after some months, unable to re-enter the old nerve plates. The resulting pattern of innervation is then far from normal, and many muscle fibres never recover at all.

It was therefore fully realized that delay in suturing was certain to lead to reduced efficiency of regeneration, but there was no unanimity concerning the respective advantages of primary and early secondary suture. The obvious arguments in favour of some delay in suture were: (1) to give time for at least some absorption to take place of the degeneration products in the neurilemma tubes in the peripheral segment and at the site of division; (2) Tello and Cajal's view that the new fibres are drawn into the peripheral stump by chemical attraction set up by the degenerated products, which reached its height two to three weeks after division of the nerve; (3) the possibility that the Schwann cells which line the walls of the neurilemma tubes regenerate rapidly after division and aid down-growth of the axonal protoplasm.

Cajal's views were adopted by Duel and Ballance (1932) with considerable success in experimental work on monkeys and in human beings, in whom Duel used degenerated autografts to repair defects in the facial nerve. These problems were, however, reinvestigated by Bentley and Hill (1936), who failed to find any evidence in favour of Tello and Cajal's theories, and their views are supported by Sanders and Young (1942). Ahernrombie and Johnson (1942) and Young (1942) do not agree with these adverse findings regarding the advantages of predegeneration, and their conclusions accord more closely with the clinical results, about which there can be no dispute. These authors found evidence that degeneration of the nerve fibres caused activation of the Schwann cells, which reached its peak between the 19th and 25th days after section; and, since Schwann cells probably play an important part in forming the junction when severed nerves are repaired, they will be more active in joining together two nerve stumps if the nerve suture or nerve graft is left a few (say 10 to 20) days to degenerate before making the repair. "In this way there would be less likelihood that the Schwann cell junction will be hindered by the prior development in the suture line of serious fibrosis. The same argument indicates the use of predegenerated grafts, providing predegeneration is short (10 to 20 days)."

Advantages of Early Secondary Suture

The clinical results furnish strong evidence in favour of early secondary as opposed to primary suture. Zachary and

Ascorbic acid preparations may now be supplied to the welfare departments of factories. The Directorate of Medical Supplies of the Ministry of Supply, Portland House, Tothill Street, London, S.W.1, has taken over the supply and distribution of these preparations.

Holmes (1946) analysed 49 cases of primary suture from a clinical standpoint, and concluded that the general standard of recovery after early secondary suture is better than after primary suture. Thus, in comparable groups, 4 out of 12 early secondary sutures of low lesions of the ulnar nerve reached nearly complete recovery, even of the intrinsic hand muscles, whereas only 2 of 13 primary sutures reached the same stage; and one of these patients was aged 7, which favoured the primary suture results, as it is generally agreed that the prognosis of nerve suture is considerably better in young individuals.

The preliminary report of the American Army neurological surgeons Spurling and Woodhall (1946) offers still more convincing evidence in favour of early secondary suture. Their figures show that primary suture resulted in 22.4% of failures, whereas early secondary suture after the wound had healed had only 5% failures, and primary healing of the wound took place in 98% after the secondary operation for formal nerve repair. They conclude that, while the results of early nerve suture show a promising trend toward normal regeneration in most of the cases treated, the high incidence of failure in primary nerve suture has been clearly proved and substantiates the directives forbidding this procedure issued during the war in the European theatre of operations. We must therefore conclude that primary nerve suture at the time of wound excision is inadvisable, the best results being given by early secondary suture as soon as the wound is healed and, if possible, in the period two to five or six weeks after injury.

There is, however, not the same agreement concerning the treatment of the nerve stumps at the time of wound excision. Spurling and Woodhall recommend that they should be roughly approximated by a sling suture, but Thomson *et al.* (1946) found that retaining sutures were harmful, because they increased the amount of fibrosis within the nerve ends and were of negligible help to the operator in subsequent identification. They consider that the nerve ends should simply be placed under the adjacent muscles for protection. The efficiency of wound excision and chemotherapy in the forward areas was manifested by the fact that comparatively little scarring was found when early secondary suture was performed in the 1,500 cases recorded by Spurling and Woodhall, so that the stumps were readily mobilized and the gaps that could not be closed by end-to-end suture amounted to less than 1%. Sufficient mobilization to ensure coaptation of the nerve ends without any tension may necessitate an extensive dissection, which is of course inadmissible at the time of wound excision, both in surgery of warfare and in that of civil life.

Spurling and Woodhall emphasize that every surgeon who participated in peripheral nerve surgery was instructed in the following generally accepted principles:

1. The suture line must be free from tension, this result being accomplished by extensive dissection, with transplantation of the proximal and distal nerve segments if indicated, rather than by traction and unphysiological flexion of the contiguous joints.
2. The proximal and distal ends must be accurately trimmed until grossly normal nerve ends were visible.
3. The transected ends must be approximated by a very carefully performed interrupted epineural suture. The use of a trans-neural or sling suture was left for the surgeon to decide.
4. Rigid haemostasis was mandatory, and was to be accomplished without the use of a tourniquet unless required by an associated vascular lesion.
5. Nerve lesions other than division were to be treated by strict conservatism.

Tantalum wire 0.003 in. (0.076 mm.) swaged upon atraumatic needles was recommended as suture material, but was not mandatory. Fine silk could be used if preferred, or if tantalum wire was not obtainable. Tantalum wire has the advantage of being radio-opaque, which, in some cases that failed to recover function, was found helpful as evidence of disruption of the nerve ends. The use of fibrin film and clot (Singer, 1945), with a tension suture only, to fix the nerve ends together does not appear to have improved results, and Thomson found that they increased fibrosis.

Gum acacia 50% has proved successful to fix skin grafts in place (Rubin, 1945), and has also been used to glue nerve ends or cable graft strands together (Klemme *et al.*, 1943).

Causes of Failure of Primary Repair

Zachary and Holmes's analysis of the causes of failure in 19 cases of primary suture which they explored is instructive.

They excluded from their total number of 49 cases no fewer than three cases in which they found that the nerve had been sutured in error to a cut tendon which were referred to the Wingfield-Morris Peripheral Nerve Injury Centre. Every surgeon has encountered similar gross mistakes of this kind, and it is not surprising to note that these authors regard poor technique at primary repair as the principal cause of failure. As primary nerve suture is definitely contraindicated as an emergency procedure, it would be productive of better results if all cases needing peripheral nerve surgery were, whenever possible, referred to special neurosurgical centres, where formal early secondary repair could be carried out by those with special experience and interest in this branch of surgery.

In carrying out early secondary suture, the proximal and distal segments of the nerve should be identified in their undisturbed surroundings above and below the lesion. Before the nerves are displaced a single marking stitch of black silk should be inserted through the epineural sheath near their cut ends to prevent axial rotation, as there is a definite possibility that the inferior results in suture of a mixed nerve, such as the ulnar, may be due to "shunting" and inability of the larger motor fibres to grow down the smaller sensory neurilemma tubes which may lie opposite them if rotation should have occurred.

Inadequate resection of the nerve ends is the next most common cause of failure, and the ends must be cut back with a fine sharp knife or razor blade until rounded glistening fasciculi are exposed in both segments. The pattern of the fascicular bundles in the ends of the nerves is then matched as nearly as possible, and close apposition made by interrupted fine silk sutures which include the epineural sheath only. The line of union must be accurate, as otherwise the regenerating fibrils will escape from the junction and form a neuroma with subsequent loss of function. Secondary suture is facilitated and rendered more secure by the thickening of the epineural sheath, which is well marked two or three weeks after division.

When loss of nerve function follows contusion without an open wound, greater difficulty is encountered in assessing the degree of injury, and we may, because of the hope that spontaneous recovery will occur, lose the opportunity of early repair if recovery should fail to take place. In the absence of any evidence of recovery the nerve should be explored within three months of injury. The appearance and feel of the nerve and its ability to transmit a weak faradic current on direct stimulation are of assistance in determining the extent of intraneural damage. In the absence of definite evidence of gross injury the nerve should be freed from any adhesions, protected from scar, and then left alone, as a surprising degree of spontaneous recovery may take place (Livingston *et al.*, 1945). A negative response to faradism when tested through the intact skin is unreliable. Learmonth (1944) found that the study of the curves of muscle excitability is of assistance in doubtful cases (Ritchie, 1944; Hoen, 1946). In partial wedge-shaped injury to a nerve, or in excision of a neuroma in continuity, great care must be taken to preserve any remaining conducting nerve bundles which give a response, the divided fascicles being adequately resected and then sutured end-to-end, after the intact portion has been mobilized sufficiently to enable them to be brought together without tension.

The prognosis is particularly bad in ulnar nerve lesions. Elkington (1944) found that this was equally true whether the lesion was near the wrist or high in the forearm, in apparent contradiction to the general rule that a lesion is more serious the higher it is situated in a nerve, because of the longer time required for regeneration after repair. One factor may be that the intrinsic muscles of the hand act as opponents to the long flexor muscles as they extend the fingers at their interphalangeal joints, through their insertions into the extensor tendon expansions.

When division of the ulnar nerve, and particularly of both the ulnar and median nerves, is done below the level of supply to the long flexors a marked degree of clawing of the fingers is produced by the then unopposed action of the long flexor muscles, whereas, though the long flexors are also paralysed in high lesions, this troublesome dissociation clawing does not occur. Seddon makes the helpful practical suggestion that the poor results after injuries of the ulnar and median

erves at the wrist might in part be explained by the fact that after repair the hand is kept flexed at the wrist to relax the suture line, which may be damaged during subsequent correction of the position. It is his practice to mobilize the nerve, if need be up to the elbow, so that it could be sutured with the elbow flexed to 90° and the wrist in the neutral position or even in slight extension.

Nerve Grafting

We have seen that end-to-end suture must be without tension, and when there is any considerable gap following the injury or resection of the nerve ends many ingenious procedures have been practised to enable the ends to be brought together. Mobilization of the segments by blunt dissection, transplantation of the ulnar nerve to the front of the elbow, re-routing the radial to the antero-medial side of the humerus, and, when associated with a compound fracture, resection of as much as 3 in. (7.5 cm.) of the shaft of the humerus have all been practised with more or less success. When a gap between the ends of a nerve cannot be closed by any of these length-gaining procedures the prognosis is exceedingly bad, as there is at present no satisfactory way of dealing with this condition, in spite of the fact that both scientists and surgeons have worked at the problem for many years. All the devices to provide a sleeve or scaffolding which would fill the gap and guide regenerating nerve fibrils into the distal stump have so far proved unsuccessful.

Homografts.—The use of nerve homografts—grafts transplanted from an individual of the same species—has yielded results which are difficult to interpret, as the regenerating fibrils grow down for varying distances into the graft and then fail to progress. Seddon and Holmes (1944) suggest that the homograft sets up an active immune reaction, such as Medawar (1945) found to be responsible for the destruction of skin homografts, preceded by a latent period during which their behaviour resembles that of an autograft. During the latent period the nerve fibres begin to colonize the graft, and in a short homograft in animal experiments may even succeed in traversing the graft before the specific immunity reaction sets in and arrests further progress, if it catches them still in the graft. Further complete failure with homografts has recently been reported by Barnes *et al.* (1946) in 8 cases. The use of stored grafts to avoid this immune reaction has proved equally unsuccessful, as they were found to provoke a foreign-body reaction which led to their removal by phagocytosis.

Autografts.—The results following the use of autografts have been more encouraging, as, though the graft dies, it preserves its original neurilemma structure, and neurotization of the autograft is predominantly regular and parallel to the graft structure, while in homografts the regenerating fibres follow an irregular and deviating course (Loyal Davis *et al.*, 1945). Autografts of sufficient size are, however, seldom obtainable in human surgery.

I have already referred to Duel's successful use of degenerated grafts. The method he employed was to cut the anterior femoral cutaneous nerve proximally and distally, and then to leave it otherwise undisturbed in place for two or three weeks to allow degeneration and enough absorption to take place before using it as a graft. Duel (1934) states that when portions of the nerves treated in this manner were used to graft defects in the facial nerve, facial response was restored in a quarter to half the time formerly required for fresh grafts. Lathrop (1946) used Duel's technique with success in 9 cases to repair lesions of the facial nerve secondary to war wounds. He employed fresh grafts of the anterior femoral cutaneous nerve in 5 and predegenerated grafts in 4 cases, and reports that the only advantage of the latter was that it was more easily handled because "its increased consistency permitted better coaptation of the suture lines"; but the rate of recovery of function was not hastened.

Bunnell (1944), utilizing the sural cutaneous nerve from the back of the calf as a fresh cable autograft, records very successful results. A bundle of short lengths of a size to match the injured nerve was used. This method has not proved so successful in other hands. Loyal Davis found that "even in the cat autogenous grafts did not heal like an end-to-end

suture. The ectodermal elements of the graft underwent a necrobiotic process, and only the mesodermal elements remained alive. The myelin degeneration process was different from Wallerian degeneration. It also seemed that the Schwann cells in the graft became necrotic, possibly as a result of ischaemia. The mesodermal endoneural cells, however, usually survived and were an important factor in the preservation of the original structure of the graft. They proliferated almost immediately after implantation of the graft, and thus paved the way for the regenerating nerve fibres which, accompanied by outgrowing Schwann cells, followed the old endoneural tubes."

Necrosis is most marked in the central portions of a large autograft, and regenerating nerve fibres to a great extent occupy the peripheral zones of the graft. Bunnell considers that this is due to the surrounding lymph having penetrated the periphery to maintain its vitality, and he believes that the success of the multiple-stranded autograft is due to the fact that lymph is able to penetrate more easily throughout its looser structure. Gutmann and Sanders (1943), however, suggest that the endoneural tubes may be too narrow to allow the effective maturation of large motor fibres, and consider that this may explain some cases of failure of cable grafts of cutaneous nerves for gaps in the larger peripheral nerves, though they may succeed, as Bunnell has found, in repair of smaller sensory nerves and for certain special nerves such as the facial.

Tendon Transplantation.—In the present state of our knowledge, however, the chances of success after grafting are so poor that, in addition to the use of an autograft, tendon transplantation should be resorted to without delay. There seems little justification for Iselin's (1945) arguments in favour of tendon transplantation as a routine measure even when end-to-end suture has been possible. He advises early muscle transplantation in all cases of division of the larger peripheral nerves before muscle atrophy; joint stiffness, and other trophic changes have had time to develop and to curtail the period of incapacity. He considers that the present practice of resorting to orthopaedic measures only after nerve repair has failed has little chance of success, because too much is required of the transplanted muscles, which, though weakened and acting at considerable disadvantage in their new positions, are expected not only to correct deformity but also to furnish movement. He urges, along the same lines as Bunnell, that the static deformity must first be corrected by tenodeses and other orthopaedic methods before the muscles are transplanted to restore mobility. Iselin believes that, even in the event of nerve repair ultimately proving successful, this result will be assisted because the transplanted muscles act as tutors while those whose action they have reinforced are regaining their functions.

Iselin's views appear to be supported by Altman and Trott (1946), who performed muscle transplantations in 23 cases of paralysis of the radial nerve, with most successful results, as the function of the hand and wrist approached normal in approximately two to three months after the operation, of which they describe some useful modifications in technique. Tendon transplantations have proved successful and have been widely practised for many years to correct the effects of radial nerve paralysis, and more recently treatment along similar lines has been devised to restore some usefulness to clawed fingers secondary to an irremediable ulnar nerve lesion, and to bring back opposition of the thumb after paralysis of the muscles concerned in that essential movement. Bunnell, in particular, has given a detailed description of this form of treatment.

Conclusion

Throughout all stages of the treatment of peripheral nerve injuries it is of great importance to remember that denervation is associated with trophic changes which affect all the structures of the limb, including the joints; and though splinting is necessary in their treatment and after-treatment to relax the paralysed muscles and to safeguard the nerve repair, the splints must be removed frequently to permit guarded exercises to preserve joint mobility and electrical stimulation of the paralysed muscles, as the one and only criterion of success is restoration of function, which is so quickly lost and so difficult to regain.

Summary

The reasons are given why delayed secondary suture of peripheral nerve lesions is likely to prove unsuccessful.

The preliminary results of surgical treatment during the second world war, which are now becoming available, furnish strong evidence in favour of early secondary as opposed to primary nerve suture.

Recent work on nerve grafts is considered.

ACUTE APPENDICITIS IN THE AGED

BY

D. GREY SIMPSON, M.B., Ch.B.N.Z.
 F.R.C.S.Eng.&Ed.

Relatively little has been written about this ubiquitous disease in the aged, yet its manifestations are often so different in patients over 60 that a description is merited. The following points are stressed: (1) The incidence, and the advanced age at which it may occur. (2) The differences in the symptom-complex, and the importance of bearing them in mind. (3) The difficulties in diagnosis and treatment. At any age surgical intervention is well worth while.

Pathology

In acute appendicitis 1 to 2% of all cases occur in patients who are over 60 years of age (Taylor, 1935; Maylard, 1920). The aetiology of the disease is the same as at other ages, but emphasis must be placed on obstructive factors, especially faecoliths. The structure of the organ has altered by the time 60 years have passed. Most of the lymphoid tissue has disappeared and fibrous atrophic changes have occurred, associated with vascular changes, causing impaired circulation and an inability to respond to the demands of inflammation for increased blood supply. Thus the devitalized organ, when subject to obstruction, rapidly succumbs to the onslaught of the infective contents and soon perforates. The omentum and general peritoneum often lack their pristine ability to localize infection, and general peritonitis results. This is withstood poorly, and a fatal termination is common.

The following summary of different series clearly demonstrates the prevalence of serious pathological changes:

		Stalker	Wood
Appendix ruptured	62%	80%
Appendix not ruptured	38%	20%

These figures show that in over two-thirds of the cases the appendix is ruptured.

The mortality is variously reported: Stalker (1940), 16%; Taylor (1935), 20%; Wood (1934), 28%; Fitch (1928), 54%. The commonest causes of death are general peritonitis and

pneumonia, while pulmonary embolism, cardiovascular accidents, cardiac failure, septicaemia, and intestinal obstruction account for a small number. Thus acute appendicitis in the aged rapidly passes to a state of gangrene, followed by perforation and often by general peritonitis, when the localizing powers are too slow or ineffective to allow of abscess formation.

Clinical Aspects

The symptoms and signs differ considerably from the usual pattern in younger patients, but nevertheless there is a fairly well defined syndrome in the aged. Pain is often poorly localized, though nearly always present, and becomes intense only when peritonitis has supervened. In the early stages it is frequently attributed to constipation, which often accompanies or precedes the attack. The taking of aperients, no doubt, adversely affects the issue.

The general reactions of nausea, vomiting, fever, and elevated pulse rate are not found, though a slight fever is recorded in some cases, especially when general peritonitis has supervened. The localizing signs of rigidity, tenderness, and pain on rectal examination are vague and inconclusive, or are absent. Thus in the early stages the patient does not appear ill and show no signs of the mischief afoot, so that even the wary may be deceived into thinking that constipation is the only complaint. The patient frequently considers this to be the trouble, and delays seeking advice. Hence many cases are not seen until peritonitis has developed.

The clinical picture is now dominated by pain and distension, while vomiting and fever are common. Intestinal obstruction is often suspected by the medical attendant, and valuable time may be lost in attempts to locate a growth. When a mass is present this diagnosis receives strong support. (In Wood's series 38% were misdiagnosed before operation as carcinoma or obstruction of the bowel.) Assistance in diagnosis will be found in a white cell count, which is often significantly elevated even in the aged, but it will greatly help if it be remembered that 1 to 2% of all cases of acute appendicitis are found among those over 60.

Treatment

It is manifest that ideals in treatment are difficult to attain when the surgeon is in doubt as to the nature of the condition before operation. If there is a confident diagnosis, a muscle-cutting incision exposing the lateral side of the caecum permits the removal of the appendix with a minimum of interference with the peritoneal cavity. Those cases showing satisfactory ability to localize the condition—i.e., "appendix mass"—are best treated conservatively, provided the symptoms subside under conditions of rest. Close observation in hospital is, of course, essential.

When appendicitis is considered possible, but there is some doubt as to the diagnosis (38% of cases according to Wood) an incision over the right iliac fossa should be made rather than a near midline laparotomy. If the appendix proves innocent, the operation can be concluded promptly by a caecostomy for relief of large-bowel obstruction. Rarely will it be necessary to close the original incision and make a near midline one in search of small-bowel obstruction.

If there is no suspicion of the appendix before operation and a near midline laparotomy has been performed, appendicectomy should be done only when the surgeon is confident of an easy, speedy removal, with a minimum of manipulation of the intestines—e.g., pelvic or ileac position of the appendix and no adhesions. When the general condition is far from satisfactory a drain down to the appendix is wiser. Taylor, in 1935, strongly advocated drainage in all cases, and particularly stressed the dangers of appendicectomy through a near midline incision.

The following case well illustrates most of the above remarks and it is recorded to emphasize the advanced age at which the condition may be successfully treated.

Case Report

A woman aged 85 was admitted to Kingston County Hospital from a pensioners' home on Aug. 8, 1946. She had been constipated for several days, but made no other complaint until a sudden attack of vomiting the previous evening. Two enemata that night produced neither flatus nor faeces. She continued to vomit greenish-brown offensive fluid, and complained of some vague abdominal pain.

On examination the old lady was very thin and dehydrated, with dry coated tongue and distended abdomen, especially centrally. She tended to hold the abdomen tight and resented palpation, but no localized pain or mass was detected. Auscultation of the abdomen was inconclusive. Rectal examination was negative, and no herniae were present. All other systems were normal. The temperature was 96° F. (37.55° C.), pulse 86, respirations 22. A provisional diagnosis of acute intestinal obstruction was made, and the stomach emptied by a Ryle tube, while an intravenous infusion of saline and plasma was administered. Two further enemas failed to produce a result, and a laparotomy under thiopentone-cyclopropane anaesthesia was made a few hours after admission. A lower right paramedian incision revealed free foul pus in the peritoneum and a sticky exudate covering acutely inflamed dilated loops of bowel. The caecum was collapsed, and a perforated gangrenous appendix was lying in the same position, free from adhesions. The appendix was easily clivered and removed. The peritoneum was drained and the abdomen closed.

Post-operative treatment, including intravenous glucose-saline, with alphadiazine 1 g. 4-hourly and 15,000 units of penicillin 3-hourly, brought about steady improvement, and the patient was discharged to the pensioners' home on the sixteenth day of the illness.

Discussion

Early symptoms were not noticed by the patient, and only when vomiting occurred (due to established peritonitis) was advice sought. The clinical picture strongly suggested intestinal obstruction, which no doubt was present in the nature of an ileus, but the cause was not diagnosed until the abdomen was opened. A white cell count before operation might have aroused sufficient suspicion of acute appendicitis to cause the preferable method of right iliac incision to be used. The remarkably eventful recovery indicates that even advanced age should not deter the surgeon.

Summary

An account of acute appendicitis in the aged is given. The incidence is 1-2% of all cases of acute appendicitis, and the mortality about 25-30%.

The pathology is a rapid development of gangrene, perforation, and peritonitis.

Clinical aspects are discussed, stressing the paucity of symptoms and signs in the first few days, and the similarity to acute intestinal obstruction and growth of the bowel in later cases.

The treatment is discussed (1) when there is a confident pre-operative diagnosis; (2) when acute appendicitis is merely suspected; and (3) when acute appendicitis is not diagnosed before operation.

An illustrative case at the advanced age of 85, with survival, is reported.

I wish to thank Mr. R. H. Franklin, consulting surgeon, for his advice and encouragement, and Dr. A. A. Cunningham, Medical Superintendent of Kingston County Hospital, for permission to publish this case.

The Medical Officer of Health of Willesden, Dr. G. F. Buchan, has presented an interesting review of his 34 years' period of office with that borough. From the days when he toured his district in a horse-drawn carriage ("thereby adding greatly to the enjoyment of life and work") to the present time, every year has seen the extension, and sometimes the pioneering, of public health facilities. Comparing the five years 1907-11 with 1941-5, the death rate fell from 11.1 to 8.3, the infantile mortality rate from 100 to 50, and the maternal mortality rate from 3.8 to 1.7. A ringworm clinic was opened in 1912 and has greatly reduced the incidence of that disease; an eye clinic followed in 1914. Already in that year the falling birth rate was being critically examined from physical, social, and economic aspects. In 1917 a midwife and home-help service began for necessitous mothers confined at home. A scholarship scheme for training sanitary inspectors, the first of its kind, which was started in 1927, is very successful and has been copied by other local authorities. Of the three health centres the first was opened in 1916, the second in 1918, and the third in 1930, attendances rising from 18,089 in 1917 to 255,962 in 1938. Plans for the extension of the health services have been worked out, but they are necessarily tentative because of the priority of housing.

Medical Memoranda

New Albumin Blood Substitutes

Known blood substitutes (salts) do not yield good results when the patient has lost large quantities of blood or is in a condition of traumatic shock. It has long been considered necessary to add a colloidal component to the salt solution of every blood or plasma substitute to give it body when injected into the blood vessels. The manufacture of artificial colloidal media as substitutes for blood is still an urgent problem. The selection is limited by the presence of foreign albumins which are biologically active; the colloidal-albumin component of the blood substitute should therefore possess no anaphylactogenic or primary toxic properties.

In our work at the Blood Transfusion Institute we have made use of a solution for intravenous transfusion which we called "colloidal infusin"; it contains an albumin product obtained from the casein of cows' milk. Casein, of course, has both anaphylactogenic and toxic properties. We set about preparing an albumin product from casein which did not possess these properties and which could be used for internal injection in large quantities. A system of fractionation of natural casein was developed to remove the substances possessing primary toxic and anaphylactogenic properties. Practically, this consists in a special method of denaturation and a weak hydrolysis of the initial natural albumin with extraction by means of an organic diluent.

EXPERIMENTAL

Before recommending colloidal infusin to the clinics as a therapeutic medium for parenteral infusion and injections we studied it on animals. Experiments on the substitution and stimulation aspects of the solution were developed in accordance with the following plan: (1) Biological test for anaphylactogenic and primary toxic properties. (2) Substitution effect on dogs whose blood had been drained in quantities sufficient to cause death. (3) A study of the dynamics of the serum albumins in patients suffering from alimentary dystrophy and treated with frequent injections of colloidal infusin. (4) The effect of non-anaphylactogenic casein on the permeability of the blood vessels in patients suffering from alimentary dystrophy and in experimental animals.

Numerous experiments on rabbits showed the complete absence of toxic properties in colloidal infusin (4% concentration) after a single injection of a large quantity (up to 2 g. per kg. weight with internal application). Subsequent internal injections of this albumin at optimum times for anaphylaxis did not produce any reactive effect in the rabbits. The testing of the solution on guinea-pigs by the classic method of producing anaphylaxis also gave negative results.

CLINICAL APPLICATION

To-day we have behind us the experience of 700 clinical transfusions of colloidal infusin given to patients suffering from various ailments (burns, volvulus, alimentary dystrophy, etc.). In many cases a second injection was given at a period dangerous for anaphylaxis, and no reactions were noted which in any way resembled a state of allergy (rash, Quincke's oedema, and other symptoms).

By using numerous successive injections of colloidal infusin we were able to obtain a rapid increase in the amount of albumin in the serum of patients suffering from alimentary dystrophy, with a corresponding increase in colloidosmotic pressure. The data obtained in experiments on animals and in the treatment of human beings demonstrate the significance of colloidal infusin in combating hypoproteinaemia in various diseases.

We now have considerable data, both clinical and experimental, on the question of the effect of colloidal infusin on the permeability of the epithelium of the capillaries of the patient. The question of the permeability of the capillaries is an important pathogenic factor in the development of many diseases. As a rule an injection of colloidal infusin noticeably lowers the permeability of the capillaries, with a pathogenic increase in permeability during the first hours after the injection. Lower capillary permeability was expressed by a lowering of the liquid filtration figure and—a most important fact—by a cessation in the pathological filtration of albumin.

Colloidal infusin is now used clinically in the following ways: as a plasma substitute in cases of traumatic shock and as a complete blood substitute in cases where there has been considerable loss of blood; as a means of treating hypoproteinaemia of various origins (exhaustion from wounds, deficiency of food,

etc.); and as a stimulant in all cases of indolent wounds. In the surgical and therapeutical clinics of the Academy Profs. H. H. Vlahos and V. I. Kazansky have made over 700 injections of colloidal infusin. Patients have proved able to withstand large doses of the solution, and its value as a substitute and a stimulant has been proved.

Monovular Twins

I would like to place on record the following case of twin labour which occurred at the Bosworth Park Infirmary, Market Bosworth, and which appears to confute the theory of X and Y chromosomes.

CASE REPORT

In a primipara aged 31 a twin pregnancy was diagnosed antenatally. This was confirmed some three weeks before parturition by an x-ray photograph, which showed a vertex and a breech presenting. A week later the breech of the larger foetus seemed to be in front of the vertex of the smaller; so by simple external manipulation the latter was made to engage in the pelvic brim.

At the commencement of labour the diagnosis of vertex and breech was confirmed, and the vertex was found to be leading. Labour proceeded normally and expeditiously up to the birth of the first twin, a girl who weighed 5 lb. 2 oz. (2.3 kg.); the placenta, however, remained *in situ*, and its normal delivery was prevented by the head of the second twin following on the heels of the first, so that the second head engaged in the pelvic brim, and the presenting part became the vertex instead of the breech. The birth of the second child was complicated by the presence of the umbilical cord of the first, which latter was no doubt responsible for the imperfect flexion of the head, which resulted in a deep transverse arrest. With the aid of forceps the second twin, a boy of 6 lb. 12 oz. (3.06 kg.), was delivered 2 hrs. 20 mins. after the first.

The after-birth came away naturally after the second twin was born, and consisted of a single bag of membranes containing two placentae. There was no visible communication between the two placentae, nor was there any evidence, either macroscopically or by palpation, of the remains of an atrophied partition of membranes, which would have indicated the fusion of two gestation sacs into one. Mother and children are all doing well.

I am indebted to Dr. G. D. Kelly for permission to publish this case.

G. H. PICKERING, M.R.C.S., L.R.C.P.

Oedema of Vulva due to Toxaemia of Pregnancy

The following case of vulval oedema obstructing normal delivery may be thought interesting enough to be put on record.

CASE REPORT

Mrs. B., a primigravida of 21 years, attended the antenatal clinic at this hospital throughout her pregnancy. She had no history of any cardiovascular or renal disease, and these systems were normal on examination. Her last menses started on June 19, 1945, the expected date of delivery therefore being March 26, 1946. At first examination she appeared healthy, her blood pressure being 110/55 mm. Hg. There was no oedema or albuminuria. Her pregnancy was uneventful until Feb. 15, when she complained of some swelling of her legs. A fortnight later, at the 36th week of pregnancy, her B.P. was 150/95. On March 14, the 38th week, her B.P. was 150/105, and there was considerable albuminuria (+ +), together with gross pitting oedema of legs and thighs, stretching up on to the anterior abdominal wall. Her face looked puffy and oedematous, but there was no oedema of her hands. She had vomited once during the previous night, but was free from visual symptoms and headaches.

On examination on admission there was also considerable pitting oedema of the vulva as well as of the legs and abdomen. The B.P. was 150/110, and there was considerable albuminuria—5 parts per 1,000. In spite of routine treatment, including fluid restriction, salt-free low-protein diet, and 3 mg. vitamin B, three times a day, the oedema did not decrease. The following day oedema of the vulva was greater but that of the legs was less. The labia majora and minora were grossly enlarged, as can be seen in the accompanying photograph. Her urine contained 6 parts of albumin per 1,000, and her B.P. was 140/110.

By March 16 no improvement in her condition had occurred; her B.P. was 140/100, albuminuria 5½ parts per 1,000, and oedema greater still. Urinary output was persistently normal and satisfactory. Caesarean section was therefore performed, the indications being a severe pre-eclamptic toxaemia not responding to treatment, with gross oedema of vulva sufficient to obstruct any attempt at a normal delivery. The classical upper-segment operation was performed, because of the impossibility of catheterization of the bladder due to the gross oedema. On opening the peritoneal cavity 1 to 1½ pints (568 to 852 ml.) of pale yellow free fluid was found. This was removed. A normal male child weighing 6 lb. 1 oz. (2.749 kg.) was delivered in good condition, and cried immediately. The mother's condition at the close of the operation was good.

Subsequently her progress was satisfactory. On the third day after operation she developed a temperature. There were no symptoms to account for this, and the oedema prevented a catheter specimen of urine or cervical swab being taken. The pyrexia soon settled with a course of sulphadiazine. The oedema subsided during the course of the next 10 to 14 days, her blood pressure rapidly fell to normal limits, and the albuminuria had disappeared after 10 days. On April 8 she was discharged from hospital in very good health. There was no oedema or albuminuria, and her B.P. was 120/85. The infant weighed 6 lb. 6 oz. (2.89 kg.), was fully breast-fed and

Showing the oedematous vulva, from a photograph taken on March 15, the day before Caesarean section was performed.

in very good condition. The mother was subsequently seen at the postnatal clinic on May 1, 1946, six weeks after delivery, when she was still well, with no trace of oedema or albuminuria. B.P. was 130/70. The child was progressing satisfactorily.

I wish to thank Mr. A. J. Wrigley and Mr. F. H. Finlaison for permission to publish this case, and Mr. M. G. Allen for the photograph.

Resident Obstetric Officer,
St. Thomas's Hospital, S.E.1.

Modification of Ochsner and Mahorner Test for Patency of Deep Veins of Calf

It is well established that before an operative cure of varicose veins can be contemplated the patency of the other venous drainage of the leg—that is, the deep system—must be proved. At present there are two standard methods of doing this. The first is that of Ochsner and Mahorner, in which an Esmarch bandage is used to occlude the superficial veins; the onset of pain on walking indicates occlusion of the deep veins. Secondly, that of Delbet and Mocquet, which is based on the anatomical facts that there is free communication between the deep and superficial veins of the calf through the gastrocnemius and soleus and that contraction of those muscles plays a large part in the onward transmission of blood from the leg. When the patient walks with the superficial veins occluded by pressure the collapse of the veins below the pressure signifies patency of the deep veins. The test as described in Hamilton Bailey's *Physical Signs in Clinical Surgery* is a combination of the principles underlying these two tests. Both are rather laborious, and the modification to be described, based on these principles, seems to me more convenient and equally effective.

THE TEST

When the incompetence of the saphenous valves has been proved by the presence of a "cough impulse" the thumb or fingers are laid over the great saphenous vein in the thigh with just sufficient pressure to occlude it. The patient is then asked to raise himself up and down on his toes, thus bringing the muscles of the calf into action. He continues to do this until either he complains of pain or the veins below the thumb are definitely seen to be emptying (this usually takes 15 to 30 seconds). The pressure in the thigh is then released, and the veins will be seen to refill rapidly from above. Any doubts as to their having emptied will be dispelled. If this emptying occurs the deep veins may be confidently stated to be patent.

This is a quick and convenient test and is chiefly of value when emptying occurs. If no collapse is seen, although the deep veins may be patent they should be regarded with suspicion. Further inquiry may reveal a history of old thrombophlebitis, which obviously contraindicates ligation.

Reviews

PROGRESS OF BIOCHEMISTRY

Annual Review of Biochemistry. Volume XV. Editor, J. Murray Luck; Associate Editors, James H. C. Smith and Hubert S. Loring. (Pp. 634, 30s.) California: Stanford University P.O. Annual Reviews Inc. London: H. K. Lewis and Co.

It is difficult to believe that nearly a year has passed since we noted the appearance of Vol. XIV of the *Annual Review of Biochemistry*. Vol. XV is appreciably smaller than its immediate predecessor, consisting of twenty-one special articles by experts instead of the twenty-eight that appeared in the *Review* for 1945. The number of pages has fallen from 772 to 616, with a corresponding reduction in the lengths of author and subject indexes. The present volume has thus returned very nearly to the size of Vol. XII, published in 1943, and has not maintained the increased girth displayed in the two intervening years. These changes in size seem to be largely fortuitous; they are certainly not due to any alteration in lay-out or typography; these are, as hitherto, clear and unpretentious, without unnecessary flourishes, which would be unbecoming in books as severe as *Annual Reviews*. The twenty-nine authors, all different from last year's, are drawn, as were the authors of the previous volumes, mostly from the United States, the home of twenty-one, who are responsible for fourteen of the articles between them. There are three chapters contributed by four Canadian authors, who this year represent the British Dominions in place of three from Australia last year. There are also three chapters contributed from this country, each by a single author, and one from Switzerland. It is a particular pleasure to find a chapter on the chemistry of the steroids by Prof. T. Reichstein and Dr. H. Reich.

The present volume repeats many of the staple features of previous issues; the authors continue to write from laboratories engaged in a great variety of different activities, from research institutions to medical schools and from university departments to industrial laboratories. The book opens with an article on biological oxidations and reductions, which is perhaps an intentional recognition of the fact that animal and vegetable organisms are primarily elaborate contrivances for securing a smooth and continuous maintenance of these particular chemical reactions, with a maximum thermodynamic efficiency and a minimum production of heat sufficient to maintain the organism at the required activity and temperature without damage. This chapter, covered by K. A. C. Elliot, is followed by one on the non-oxidative enzymes by A. M. Wynne; the biochemical ball is thus opened by two Canadians. After an article by S. Peat of Birmingham University, on plant carbohydrates, a subject on which members of Prof. Haworth's school are particularly fitted to write, we return to the usual regular accounts of the chemistry of certain essential nutrients. This year, as before, we have chapters on the chemistry of the lipids (J. B. Brown) and of the proteins and amino-acids (T. L. Meekin and R. C. Warner), as well as articles on the metabolism of carbohydrate (G. F. and G. T. Cori), of fat (W. C. Stadie) and of proteins and amino-acids (D. Rittenberg and D. Shemin). In the last-mentioned chapter reference is made to the very important work of Umbreit and Gale and their respective colleagues, working on opposite sides of the Atlantic, which has resulted in identification of the co-enzyme of tyrosine decarboxylase with pyridoxal phosphate. Thus, another "B vitamin" has been fitted into an enzyme system essential to intermediary metabolism, but this time, unexpectedly enough, the metabolism of protein and not of carbohydrate.

Vitamins, surveyed by R. A. Dutcher and N. B. Guerrant, are this year covered in a long chapter of 74 pages, the water-soluble and fat-soluble vitamins having been hitherto separately treated. Two contiguous articles, one on photosynthesis (C. S. French) and the other on plant respiration (W. C. James), bear witness to the steady maintenance of interest in vegetable biochemistry, as indeed do also four other chapters, though we are sometimes inclined to forget that bacteria and the many problems arising from their symbiotic or parasitic activities are of vegetable origin. These four chapters are concerned with growth factors for micro-organisms (E. E. Snell), the biochem-

istry of yeast (C. Neuberg), bacterial metabolism (H. A. Barker and M. Doudoroff), and immunochemistry (E. A. Kabat). Perhaps it is not quite fair to place this last chapter under the wing of the plant physiologist and thus remove it from the sphere of influence of the biochemist, who will doubtless also lay claim to the chapters on viruses (N. W. Pirie), chemistry of the hormones (H. Selye and H. Jensen), the biochemistry of teeth (H. M. Leicester) and the steroids, to the last of which reference has already been made.

An account of recent work on pressor amines (W. H. Hartung) strikes a slightly pharmacological note, though it is concerned primarily with the inactivation and detoxication of these substances. The contribution on organic insecticides (W. M. Hoskins and R. Craig) deals with matters of the most far-flung importance in medicine, as well as being highly topical, because of the bearing of insect control on the epidemiology of disease, more especially in wartime and in hot climates.

It will be seen that the 1946 *Review* maintains the catholicity of interest and the high standard of expert knowledge, as witnessed by the names of the authors, that have characterized previous volumes; yet one is left with a slight sense of misgiving. We have the *Annual Reviews of Physiology* as well, to say nothing of surveys of enzymology and chemistry, both pure and applied, some, like this one, from the United States, others from Britain, and some in competition from both sides of the Atlantic. In addition, there are such admirable surveys, periodical but not necessarily strictly annual, as *Vitamins and Hormones*, now in its third number, and one cannot help wondering whether some kind of survey of surveys might not help to reduce their number and thereby also the labour of those who wish to keep up to date as well as of those who are trying to help them to do so.

A. L. B.

OPHTHALMIC SURGERY

Eye Surgery. By H. B. Stallard, M.D., F.R.C.S. (Pp. 444; 338 illustrations, 50s.) Bristol: John Wright and Sons, Ltd. 1946.

It is some thirty-five years since a book on the surgery of the eye has appeared in this country. Mr. H. B. Stallard's substantial volume entitled *Eye Surgery* is therefore welcome. His contribution, as he explains, was written at sea, in military transports, and in camps, amidst many and various distractions, and without any access to ophthalmic literature. This makes it essentially a record of personal methods and experience, but it is none the less a trustworthy guide to current practice. Much that is obsolete (and which finds a place in books produced under more leisurely conditions) is mercifully absent. Inevitably, however, experiences with war casualties tend to colour the writing. Many of the 338 illustrations have been drawn by the author, and this again lends strength to the text, as professional artists cannot illustrate the text so pertinently as the surgeon himself if he has the skill to do so.

The introductory chapter, with its stress on detail, beginning with the personal qualities of the surgeon and ending with the dressings, is characteristic of the book as a whole. A short chapter on anaesthesia and analgesia is followed by an extensive account of the eyelids and reconstructive surgery. This occupies almost a third of the text on operations, and it is here that the effect of the author's experiences during the war are seen at their fullest. The chapter on the lacrimal apparatus contains many personal departures from the standard operations, which, however, are not overlooked. The chapters on the extraocular muscles, on the conjunctiva, cornea, anterior chamber, and sclera are more orthodox in scope, and this also largely applies to the chapters on the iris, the lens, glaucoma, and the retina, choroid, and vitreous. The two concluding chapters deal with traumatic surgery, civil and military, and with the orbit.

Attention to minutiae is the essence of competent operating, and the author's stress on detail makes his text valuable not only for the learner but for the accomplished practitioner. There is much with which individual surgeons will disagree, but the practice of eye surgery as expounded in this book is consistent. Learners will be grateful for the clear indications given on operations for cataract, and few surgeons will quarrel with Mr. Stallard's advice—contrary to textbook teaching—that in the occasional event of the knife being entered with the cutting edge downwards the operation should be postponed, and not

continued at the risk of mutilating the iris. Whether one needle bent at an angle should be used in operations with two needles seems a moot point. Most surgeons prefer to avoid angled instruments, since direction is less certain than with straight instruments.

In post-operative complications in glaucoma delayed reformation of the anterior chamber is undoubtedly a serious matter, but few surgeons will subscribe to the rather pessimistic view taken by the author, which is almost reminiscent of the conception of "aqueous calamity" of the ancient writers. The author likewise probably takes an extreme view in believing that malignant melanomata of the choroid are not so radiosensitive as glioma of the retina. Many pathologists regard melanomata as particularly susceptible to radiation, and believe that the evil repute of the melanomata is due to the early metastases that they give. Few surgeons who have tried it will agree that a Krönlein operation is particularly valuable for the removal of retro-ocular new formations. It is, however, easy to find points from which to dissent in an exhaustive practical treatise. The more significant thing is that here is an adequate text on contemporary operative technique.

PARATUBERCLE BACILLI

Inventaire et Description des Bacilles Paratuberculeux. By Paul Hauduroy. (Pp. 168. 200 francs.) Paris: Masson et Cie. 1946.

If the painstaking collection and recapitulation of facts without any attempt to draw conclusions from them is a worthy scientific purpose, then Prof. Hauduroy may well be congratulated. In his monograph entitled "An Inventory and Description of the Paratubercle Bacilli" he has copied, mainly from the papers of the original authors, a description of no fewer than 160 members of this group. He has wisely refrained from committing himself to any classification of these organisms, realizing that the criteria necessary for such a purpose are still far from clear. He has contented himself rather with defining a problem, and has left it to others to seek its solution. He is plainly intrigued with the potential pathogenicity to laboratory animals of a few strains of paratubercle bacilli; and he has included a chapter on the properties of the tuberculin-like substances, or paratuberculins, that these organisms may produce. The work is for a limited public, intended purely for reference purposes, and will necessarily find a place in the libraries of those whose interest is in systematic bacteriology.

SOME CONTRASTS AND COMPARISONS

Doctors Differ. Five Studies in Contrast: John Elliotson, Hugh Owen Thomas, James Mackenzie, William Macewen, R. W. Philip. By Harley Williams. (Pp. 249; illustrated. 12s. 6d.) London: Jonathan Cape. 1946.

Here is a new and fascinating approach to modern British medical history. The theme of the book is that "the way to make progress in medicine lies through different temperaments." This method is fully justified in the vivid accounts Dr. Harley Williams gives of men opposed in temperament but complementary in achievement who were responsible for some of our most important advances. The first section is concerned with the tentative efforts towards a medical psychology in which such men as Mesmer, Charcot, Freud, and Coué were engaged. Elliotson of University College Hospital is singled out as the pioneer here. His was a brilliant and erratic career well described with incidental sketches of the men with whom he came into contact and generally into conflict. U.C.H. men will be astonished but diverted to read of the strange doings there in its early days, when more or less public séances took place, conducted by Elliotson assisted by two "magnetic" sisters. Wakley of the *Lancet* comes prominently into the picture, first as a stout supporter of Elliotson the innovator, but later a bitter opponent of a "charlatan and exhibitionist." Dr. Williams shows that Elliotson was a real pioneer with the curiosity and perseverance of the scientist, but he was diverted from the track which might have led to a substantial advance in psychology by his belief in an actual fluid magnetism which operated directly or indirectly on certain sensitive people. But there was much that was admirable in Elliotson, and we are reminded that Thackeray dedicated to him the second volume of *Pendennis*.

In the section "Rural Healers" the story of the evolution of orthopaedics from bonesetting is told, illustrated by the

personalities of the Thomas family—Evan, the village bone-setter; H. O. Thomas, his son and the uncle and master of Robert Jones. We have H. O., the fiercely independent and quarrelsome craftsman, and Jones who made friends wherever he went. There are also thumbnail sketches of Hutton, the bonesetter, and Wharton Hood, who sat at his feet.

The next contrasted pair are Osler and James Mackenzie, who were "largely responsible for the great revival of internal medicine, as much a feature of the 20th century as was surgery in the 19th." The two very dissimilar characters are very well done. Then come Macewen and Victor Horsley mainly in connexion with brain surgery. The reviewer found this section particularly attractive, having known and revered both men and most of those mentioned by the way. The two chief actors are described at length with obvious relish: Macewen the self-sufficient—"I am not a co-operator"—who acknowledged no master save Lister, to whom he had acted as house-surgeon; Horsley who "worked gregariously and loved to exchange ideas." The nature of the work of these men is shown as complementary, and justice is done to the genius of both except in one particular. Horsley in his latter days developed a strong interest in politics of an advanced kind. He was adopted as a Liberal candidate for Parliament, but quarrelled with his supporters and resigned. The author says, "Few men aroused more antagonism for their theories of life and more love for their personal qualities." Casting his mind back, the reviewer does not think that love was the sentiment aroused by Horsley—rather admiration and respect. And Dr. Williams does him less than justice when he says he was a "failure as a politician," for he overlooks Horsley's great achievement as a medical statesman more responsible than any other individual for the revolution in the constitution of the B.M.A. which transformed it into a vigorous democratic body with a constitution of which Horsley was the main inspiration. This section has well-timed references to Hughlings Jackson, "the philosopher of the nervous system," and to Rickman Godlee, who was the first to operate on a brain tumour.

The final section is devoted to the fight against tuberculosis, the leading and contrasted figures being Robert Philip of Edinburgh and Trudeau of the U.S.A. Why and how these men dedicated their lives to preventive medicine with special reference to tuberculosis is told with gusto and with a spice of sly malice in regard to Philip which will be greatly enjoyed by those who knew him.

In offering thanks for a very interesting book, a special word of praise is due to the illustrations—mostly portraits. That of Philip is literally lifelike. The reviewer wishes, however, that the portrait of Macewen could have shown him as the commanding and handsome figure he was in his old age—if Macewen can be said to have had an old age.

A.C.

Notes on Books

The Ministry of Health has published a pamphlet *You and Your Children* (H.M. Stationery Office; 6d.) reproducing B.B.C. talks by a woman medical psychologist (Dr. Doris Odum). These gave simple hints on the handling of normal children—their fears, fads, and fancies—and the problems that arise in every family.

A full account of the Royal Cancer Hospital mechanically sorted punched card index system has been compiled by Dr. D. W. Smithers, Mr. K. M. H. Branson, and Dr. H. O. Hartley. Applications for copies should be made to the Secretary of the Royal Cancer Hospital, Fulham Road, London, S.W.3.

A volume of 126 pages, *The League Hands Over*, has been issued from Geneva and is obtainable in London from Allen and Unwin, Ltd., at 2s. The last Assembly of the League of Nations has met and has been dissolved and this little book is meant to illustrate why and how the work goes on. It records briefly what the League did during the war and gives extracts of the speeches delivered during the 21st session held in April, 1946.

The Commonwealth Fund of New York has issued a booklet entitled *Eight Years of Public Health Work*, by Dr. HARRY E. HANDLEY and Miss CAROLINA R. RANDOLPH. The area covered in this report is that of Jones County, Mississippi, and the period 1937-44. The topics considered include sanitation of the community, the child under school age, the school child, the health of the adult, and collection and tabulation of vital statistics. The London publisher is Geoffrey Cumberlege and the price is 3s. 6d.

NEONATAL DIARRHOEA

The publicity which the outbreak of diarrhoea in the maternity department of the Leicester City General Hospital has received in the lay Press again focuses attention on a problem to which we have referred from time to time.¹ Enteritis in infancy is nowadays divided into neonatal diarrhoea, sometimes called epidemic diarrhoea of the newborn, and the gastro-enteritis of older infants. Outbreaks of diarrhoea in the nurseries attached to maternity units have been frequent in the large cities of America, and particularly in New York, but have rarely been encountered in this country, though medical officers of health and bacteriologists have been specially requested to report any such incidents.² There may be a certain hesitancy in reporting trouble in maternity units just now on account of the great shortage of beds and the natural unwillingness to attract attention to a condition which may necessitate closing down the unit for a period. But primary neonatal diarrhoea is a highly fatal infection, and infantile deaths do result from it. However, the mortality rates in the neonatal period have shown a marked decline during the past five or six years, and it is therefore unlikely that this serious infection has hitherto been common in this country. Incidentally, there is no indication that it is associated in any way with malnutrition.

The problem, however, has been complicated during the past few years by the occurrence among adults of a non-bacterial infectious enteritis which has been particularly prevalent in maternity departments. A typical example was reported in this *Journal* by Brown, Crawford, and Stent.³ The persistence of this infection in maternity units is probably related to the rapid turnover of patients, so that fresh fuel is continually being added to the fire which in consequence keeps smouldering on, flaring up periodically into more serious outbreaks. This infection, characterized by profuse watery diarrhoea of one to four days' duration with slight pyrexia, may affect a high proportion of both mothers and nursing staff, but its incidence among babies is usually much less (around 10%), and as a rule it is a mild infection in the baby, although deaths have occurred, usually in weakly or premature infants. This is the disease which apparently has affected the maternity units where both mothers and nursing staff were being attacked, but the high mortality rate among the infants at Leicester suggests that the infection there may be the true epidemic diarrhoea of the newborn.

The aetiology of the condition is still obscure. Intensive studies on the bacterial flora of affected infants have failed

to show the presence of any accepted pathogen, while there is no evidence that the toxins of such bacteria as *Staph. aureus* or *Cl. welchii* play any part in the pathogenesis of the infection.⁴ An interesting hypothesis has been put forward by Gale,⁵ who found that some strains of *Str. faecalis* actively produced tyramine from tyrosine and that tyramine was toxic to young rats which had not yet developed the specific detoxicating enzyme. Babies in the first few months of life also lack this enzyme, and as active tyramine-producing strains of *Str. faecalis* have been found in the stools of babies with neonatal diarrhoea it was suggested that these organisms might be causally related to the condition. That *Bact. coli* and other Gram-negative bacilli may also be involved is suggested by the finding of *Ps. pyocyanea* as the predominating organism in an outbreak of neonatal diarrhoea⁶ and of *Bact. neapolitanum* in 90% of cases of gastro-enteritis in older infants.⁷ Cruickshank⁸ has put forward the view that many of the types of diarrhoea seen in infants may be associated with potentially pathogenic variants in the coliform group.

The possibility that a virus may be involved cannot of course be excluded in spite of some negative findings. A few years ago two American workers⁹ claimed to have isolated from the stools of cases of neonatal diarrhoea a filtrable agent which produced diarrhoea in inoculated calves. This filtrable agent was unusual in that it resisted heating at 100° C. for five minutes. However, the claims of these workers have not apparently been substantiated. Buddingh and Dodd¹⁰ have described a syndrome of stomatitis and diarrhoea in infants from whose mouth lesions a virus-like agent was isolated, but their syndrome does not correspond with the usual clinical features of neonatal diarrhoea as seen in this country.

While aetiology still remains a mystery, prevention and control of the infection seem to be closely linked with breast-feeding of the infant and a high standard of hygiene in the nursery. The breast-fed baby is not immune to epidemic diarrhoea, but outbreaks are rare and usually mild in character in units where over 90% of the babies are wholly breast-fed, as we understand is the case at both Oxford and Leicester. In one outbreak Ormiston¹¹ reported a fatality rate of 14% among breast-fed babies and of 60% among artificially fed infants. In another outbreak⁶ in a unit where at the time only 12 out of 30 babies were wholly breast-fed these 12 babies alone escaped infection; the remaining 18 all developed diarrhoea and all died. If supplementary feeds have to be used, great care must be taken to see that bottles and teats are washed, and preferably sterilized, immediately after the feeds so that bacterial contaminants have no opportunity to grow and to produce toxic substances. One maternity unit has dispensed with feeding-bottles altogether for supplementary feeds or extra fluids and uses the spoon instead. Another common practice of housing all the babies in a communal nursery that is frequently overcrowded might well give way to the more

¹ *Lancet*, 1941, 2, 590.² *British Medical Journal*, 1944, 1, 631.³ *Lancet*, 1943, 2, 758.⁴ *J. Path. Bact.*, 1945, 57, 239.⁵ *Arch. Dis. Child.*, 1945, 20, 145.⁶ *Amer. J. Publ. Hlth.*, 1943, 33, 1451.⁷ *J. Pediatr.*, 1944, 25, 105.⁸ *Lancet*, 1941, 2, 583.⁹ *British Medical Journal*, 1944, 1, 595; 1945, 2, 189.¹⁰ *Monthly Bull. Min. natural arrangement of having mother and baby together, particularly where the maternity department is made up of small, four- or six-bedded units. Premature babies should be kept singly or in pairs in cubicles, for they are particularly susceptible to any kind of infection.

Despite all these precautions it has usually been found that the only procedure which will terminate an outbreak of neonatal diarrhoea is closure of the maternity unit, and it is wise to take this somewhat drastic step early rather than late. Control of the diarrhoea of adults which secondarily affects both breast- and bottle-fed babies presents considerable difficulties. The available evidence indicates—recent Oxford experience is in accord—that the infection is airborne, therefore good ventilation should be maintained at all times, even when the outside temperatures drop to a low level. Again, special care must be taken to protect the premature infant. Closure of the unit will, temporarily at least, cut short an outbreak of this type, but unfortunately the disease is often endemic in the area and may light up again with fresh admissions to the hospital. Treatment of the severe form of neonatal diarrhoea is disappointing. Both good and poor results have been reported with sulphaguanidine and succinylsulphathiazole. Intravenous fluid therapy, using Hartmann's solution plus 5% glucose and half-strength serum or plasma alternately, has proved very valuable in the dehydrated older infant and should be tried more often. It could be used, probably combined with oxygen therapy, even in very young babies. Such treatment requires expert team-work by medical officers and nursing staff, and mobile teams might well be utilized to cope with outbreaks in hospitals where such experienced personnel are not available.

MENTAL HEALTH LAW REFORM IN SCOTLAND

The National Health Service (Scotland) Bill, like the Act for England and Wales, will bring about many changes in the administrative pattern of mental health services. The Bill would make the main mental treatment and mental deficiency services part of the new hospital and specialist arrangements. It would lay a duty on the Secretary of State "to co-ordinate and supervise the administration by education and local health authorities of their powers and duties with regard to defectives." Local health authorities would be responsible for the ascertainment of mental defectives and for the provision of "suitable training or occupation for mental defectives who are under guardianship." The Bill would involve amendments and repeals of varying extent to the Lunacy (Scotland) Acts, 1857 to 1913, and the Mental Deficiency (Scotland) Acts, 1913 and 1940. It would also provide for the statutory disappearance of the word "asylum" and the substitution of "mental hospital." The publication of the Scottish Bill gives a new interest to the report¹ issued a few months ago by a Departmental Committee which was appointed in February, 1938, by Dr. Walter Elliot, then Secretary of State for Scotland. The Committee, with Lord Russell as chairman, was set up to inquire into the law relating to lunacy and mental defi-

ciency and to report what amendments it considered necessary as a preliminary to the consolidation of mental health law in Scotland.

The Committee is not in favour of a special qualification in psychological medicine for medical practitioners signing certificates for the purposes of detention. It suggests rather that the reforms in the training of students advocated by the Goodenough Committee should be carried out so as to ensure that every medical practitioner will in future be adequately equipped to certify under the Lunacy Act. Any qualified medical practitioner on the *British Register*, in the Committee's view, should in law be competent to grant certificates under either the Scottish or the English Lunacy Acts, but if there are in fact any legal or administrative difficulties these should if possible be removed. A specific statutory definition of the word "lunatic" is not desirable, but it is recommended that the terms "lunatic," "insane person," and "person of unsound mind" should be replaced by the term "mental patient." "Idiots" should be transferred from the purview of the Lunacy Acts into that of the Mental Deficiency Acts. The term "mental patient" would apply to any person who on account of mental illness is certified by two medical men to be a person requiring detention for care and treatment. Care and treatment should be the operative words, and so far as possible compulsory detention should be applied only when the patient is unable or unwilling to consent to such care.

The system of voluntary treatment which has been used in Scotland for nearly a century should be continued. On temporary provisions the Committee proposes to follow the English Act of 1930. It also agrees that the reception procedure should be simplified and that opportunities should be provided for early treatment for a limited period, as in the voluntary and temporary provisions of the English Act. Compulsory detention for prolonged treatment should be covered by the authority of a judicial order. Medical certification and the provision of hospital care are entirely medical matters and should be in the hands of some branch of the health department of the local authority. The petition to the sheriff for an order in respect of both lunatics and mental defectives requiring assistance should be presented at the instance of the local authority. In considering a petition for an order under the Lunacy Acts the sheriff should be authorized to proceed on lines somewhat similar to those laid down by English law. The Committee would also apply the English private patient procedure to all patients, and pending the result of inquiries would institute an interim order. The present emergency certificate which is valid for only three days should be valid for seven days, like an English urgency order. The present safeguards against improper detention are thought sufficient.

Senile patients present an increasingly serious problem. The shortage of accommodation for mental patients generally is due to the accumulation of patients who have not recovered and of elderly patients whose mental deterioration has made them too difficult to look after at home. It is suggested that asylum authorities might be empowered, though not required, to make special provision for such patients in a separate section of an institution, or even a completely separate provision. Senile patients who do not require prolonged institutional care should not be certified

but should be provided for along the lines of the English Mental Treatment Act. Persons who are senile but not so mentally ill as to be certifiable form an important group for which some provision may be required to be made by the public health authorities.

The Committee hopes that a special department of the Central Health Authority will deal with all branches of mental health. The General Board should, in its opinion, have power to order the transfer of a mental patient from one place to another when this is necessary or desirable in his interests but the person responsible for his detention does not make the necessary application. The relative position of the Board and the local authorities in the management of district asylums should be clarified. The English procedure by which the visiting committee of a new asylum submit draft rules for its government through the Board should be copied. The Committee would require the consent of the Board or of the Secretary of State to the dismissal of the medical superintendent of an asylum as well as of a certified institution.

Medical superintendents should have power to grant patients leave of absence for short periods at their own discretion, and leave on probation for longer periods with the sanction of the Board, but no person committed as a dangerous lunatic should be liberated temporarily without the sheriff's authority.

Broadly speaking, the Committee would assimilate the Scots law to that of England in regard to voluntary and temporary patients. It stresses the importance of having fully qualified staffs in charge of observation wards attached to general hospitals. It also recommends the creation of one centrally situated institution for Scotland for the reception and treatment of dangerous lunatics. This should be equipped, managed, and financed as part of the State Asylum for the detention of criminal lunatics. The Prisons Division of the Scottish Home Department should cease to have any control over the State Asylum, and full responsibility should be transferred to the General Board of Control. It is hoped that before long criminal and dangerous lunatics will be detained in a suitable building, not just part of a prison, and large enough to keep such patients out of ordinary asylums.

Also urgently needed is a State institution separate from the State Asylum for dangerous or violent mental defectives. In the definition of mental deficiency the Committee approves the English classification, except that they would leave out the class of moral defectives and call the feeble-minded, imbecile, and idiot classes Grades A, B, and C, respectively. Educable children should not be described as mentally defective, and their mental condition should not be classified until the age of 16. The Committee mentions another class of adolescents who display distressing symptoms of unstable disordered behaviour and are regarded as social misfits but whose mental capacity and conduct touch only the fringe of insanity, mental deficiency, or criminality. No suitable treatment appears to exist for this group, and the Committee suggests that the legislature might at the earliest moment devise some provision which will submit such persons to training and supervision in a colony or institution in which medical and psychological treatment will be available.

Local authorities should, in the opinion of the Committee, be compelled to carry out their duty of ascertainment, and should be authorized to deal with mentally defective children under 5, but only with the consent of the parent or guardian. The Committee would discontinue the present arrangement under which children found unsuitable for education in special schools and classes are passed on to the public assistance authority. The duty of providing education and training for all trainable defectives up to 16 should be laid upon the education authorities, who should be obliged to employ a psychiatrist, a psychologist, and at least one psychiatric social worker. It is not recommended that all mental defectives capable of useful training should be under compulsory control and supervision and required to attend at training and educational centres up to the age of 18. Mental defectives capable of remunerative occupation at 16 should be exempt from compulsory attendance. For those not so capable training facilities should be provided as part of the system of education, perhaps under the Disabled Persons (Employment) Act, 1944. The continued care and training of mental defectives over 18 should become the duty of a composite mental health committee, on which the interests of education, public health, and public assistance should be represented.

The Committee recommends the setting up of a central index with notification of ascertained defectives by the education authorities. Information from the index should be available only to local authorities and public prosecutors, who would be obliged to inquire whether the name of any accused person is on the index and, if it is, to see that the court knows of the fact.

Prof. D. K. Henderson, a member of the Committee, made a number of reservations. He thinks that the adoption of the English Mental Treatment Act would unnecessarily complicate the status of the voluntary patient, who at present can be kept in hospital if he loses his volition but who under the English rules would have to be discharged after 28 days. He would go further than the Committee and amend the Mental Treatment Act so that all non-voluntary admissions could have temporary treatment for a year without certification. He is also doubtful about the possibility that the education authority will be given too much responsibility in matters concerning the mental state of defectives, which is a question for the health authority. Supported by Lord Provost John Phin, he suggests that directors of education should continue to supervise all educable defectives between 5 and 18, but that all other children should be under the jurisdiction of the health authority.

A MORAL ISSUE

As might have been expected, the medical profession as a result of the plebiscite has had what is usually described as "a bad Press." The British Medical Association is by now used to having its actions and views widely misinterpreted. There can, for example, be no justification for this accusation of the *Times*: "... it is evident that the B.M.A. intends to persist in the rather reckless and emotional agitation which has contributed in no small measure to the outcome of the ballot." The *Times* leader

writer goes on to say of general practitioners: "Yet they do not seem to recognize that no comprehensive medical service can be made to work without a considerable transformation in their personal circumstances, a transformation which by collaboration they could help to plan on constructive lines." On the contrary, it is because practitioners recognize what is euphemistically described as "a considerable transformation" and not because of any "reckless and emotional agitation" that the results of the plebiscite are what they are.

In the face of so much hostility medical men may well have felt discouraged during the past fortnight to find so little sympathy for their case and so little understanding on the part of the Press of the roots of their opposition to Mr. Bevan's Bill. It was therefore heartening to discover in the independent Sunday newspaper, the *Observer*, a leading article which put the case of the medical profession in a way which showed intimate understanding of its real position: "The impression given by many criticisms is that they [the doctors] are a set of old fogeys, blindly obstructing the tide of progress and putting their own interests before the health and social welfare of the nation. This is an unfair picture of the resisters and their motives. They have a case which should be heard. . . . The charge that they are defying Parliament has no legal substance." The article goes on to describe the wide powers of the Minister to make regulations and orders, to explain the reason why medical men so strongly object to the basic salary, and to see in the resistance movement "a conviction that the Act represents the first stage in a Socialist policy which would eventually transform the character of medical practice as a free profession and profoundly injure the personal relationship of doctor and patient." The *Observer's* leader points out that with the present Act a Minister who shared the wish of a strong section of the Labour Party for a whole-time fully salaried service, could translate this wish into action without further legislation. A notable contribution to the controversy is concluded by this paragraph:

Inveterate planners are impatient of principles: having set their heart on a scheme they want above all to make it work. They are more interested in the results expected from it than in the methods employed, however harshly these may bear on human scruples or human relationships. There is no doubt that a National Health Service is greatly needed, and that it could bring great benefits to the community. The resisting doctors recognize this: but the present Act seeks to obtain benefits by methods which they cannot reconcile with their conscience and sense of medical duty. They are standing on a moral issue, and for this they should be given credit, even by their opponents.

In our correspondence columns this week Dr. Alan Maberly writes: "There can be no doubt that this is a moral and ethical issue of the first importance." Other correspondents are just as clear about the principles which have determined the policy of the Association. The doctors who answered "No" in the plebiscite are standing on a moral issue, and for this "they should be given credit."

We fear it will be some time yet before our critics will extend us this credit, but believe that in the course of time they will slowly and reluctantly be compelled to realize the truth of the issue so clearly placed before the general public in the statement quoted from the *Observer*.

TRAVEL AND DISEASE

From the earliest historical times the desire to trade, to dominate, to convert, or to satisfy an idle curiosity has impelled men to travel far and wide over the earth. Besides bearing their culture to distant lands they have also, as Dr. Findlay points out in an article on p. 979 of this *Journal*, spread their diseases. Modern transport facilities have enormously increased the likelihood of diseases spreading, and in particular the speed of aeroplanes permits not only the transport of an infected passenger to another country and his entry into the new society before the disease becomes apparent, but also the carriage of vectors of certain diseases—vectors that would previously have perished in the course of slower journeys by ship.

The mosquito-borne diseases yellow fever and malaria are particularly dangerous in this respect, but fly-borne infections may also present a problem, as well as trypanosomiasis, dengue, and the insect-transmitted encephalitides. Tsetse flies share with man a liking for swiftly moving vehicles, whether train, motor-car, or bicycle, and they have been reported in aeroplanes. Mosquitoes, too, are not averse from air travel, as Dr. Findlay mentions, and have survived flights of over 9,000 miles at heights of 10,000 to 12,000 feet. Traffic on the new motor roads in Africa has been responsible for spreading diseases as diverse as gonorrhoea, bilharziasis, and relapsing fever.

The prevention of transport by aeroplane of the insect-borne diseases, though a comparatively simple problem, is of a greater magnitude than might at first appear. Schemes for keeping aerodromes and their neighbourhood clear of the mosquito's breeding-grounds require large staffs if they are to work satisfactorily. A single aerodrome may cover several square miles—a large area to be kept perfectly drained in countries subject to tropical rains—and nearby native villages may require spraying with insecticides and supervision of their wells, drains, tanks, and ponds. The scrupulous application of insecticides to the interiors of aeroplanes and to the passengers and crew is essential. In addition, all travellers must be immunized against yellow fever not less than ten days and not more than four years before entering a locality where the disease is endemic.

There can be no doubt that the measures required can be adequately carried out only by an international organization. Many countries on international air routes—and perhaps particularly those where the insect-borne diseases are chiefly endemic—have neither the money nor the staff to provide adequate control. The wealthy countries are quite as concerned as the poor that the spread of disease should be checked, and there is no reason why contributions to this end should not be proportionate to a country's income. The World Health Organization of the United Nations would seem to be the most suitable body to undertake this work. The staffs appointed by it would be responsible to W.H.O. and only secondarily to their own governments.

A further argument favouring an international attack on the problem is the urgent necessity for preventive measures. The schemes put into operation during the recent war have in many cases lapsed, particularly in tropical countries. Wind and rain and neglect are combining to destroy the work built up at such great cost; severe damage can overtake a drainage system in a season if it is not attended to; mosquitoes return to their old haunts to breed as soon as the opportunity occurs. Again, it seems that there is not only confusion about the yellow fever certificates and who is empowered to sign them, but black market forgeries are available for those who want to avoid being immunized. This sort of trafficking requires international control for its suppression.

HOSPITALS' BALANCE SHEET

The execution morning may not be far distant, but there is nothing of the atmosphere of the condemned cell about the record of the London voluntary hospitals during 1945. The *Statistical Summary*, which King Edward's Hospital Fund presents,¹ is a dry enough compilation, but as with Dr. Johnson's friend, Oliver Edwards, "cheerfulness is always breaking in." It is, of course, true that in 1945 the Government proposals for the future of hospitals had not been promulgated, but the Government came into power in the middle of that year, and its programme could be anticipated. On the other hand, the cessation of war may well have evoked a spirit of thanksgiving which took the form of enlarged gifts to hospitals. However it may be, the subscriptions and donations to 164 voluntary hospitals in London in 1945 reached £1,276,000, being £135,000 more than the year before. Not only so, but in spite of death duties, high taxation, and other adverse economic circumstances, legacies rose to £676,000, an increase of £121,000 on the year. Mr. Bevan, in a recent speech, mentioned a voluntary hospital in his own mining district of South Wales and said that as a miner he paid 4d. a week to the hospital, as did all his fellows, not as a voluntary act, but from the necessities of their occupation, so that in this way the miners contributed 97.5% of the hospital income, and only 2.5% was contributed by the charitable, yet it was the charitable, he added, to whom the vote of thanks was accorded at the annual meeting. No proportion like this holds good in London hospitals. The voluntary gifts, leaving entirely out of account patients' payments, contributory schemes, and the like, account for just over one quarter of the total income. Patients' payments, including patients out and in, pay-bed patients, and patients coming under contributory schemes, account for just under one-third of the income, and the remainder is made up by payments from local authorities and dividends on investments. On the whole, the smaller the hospital the larger the proportion of voluntary contributions. Thus in the twelve hospitals with medical schools the proportion of voluntary gifts is 21.4% of the total income, whereas in the group of the smallest general hospitals, those with 50 or fewer beds, the comparable figure is 31.8%. The highest proportion of voluntary giving is to children's and maternity hospitals, and the lowest to orthopaedic and cancer hospitals.

On the other side of the account, however, hospital maintenance expenditure is steeply rising. The cost of salaries and wages in 1945 was up by a quarter of a million on the figure for 1944; in the teaching hospitals alone it was up by £100,000. This increase is accounted for not only by rising prices, but by increased services, for over 30,000 more in-patients were in the hospitals in 1945 than in 1944, and nearly 200,000 more out-patients were making attendances. Here it is necessary to read between the figures. Increased income is not keeping pace with increased costs. Thus while 68 general hospitals rejoice in a surplus and only 29 show deficits, the total deficit of those 29, £143,000, is more than the total surpluses of the others. Moreover, a number of hospitals show no balance on one side or the other, offsetting an excess of expenditure by transfer from free legacies; and, on the basis of sound hospital finance, these ought also to be ranked as hospitals in deficit.

The *Statistical Summary* gives particulars of the average length of stay of patients in hospital. In the general hospitals the average duration in 1945 was 18.3 days, and in

the special hospitals 29.5 days. In the medical school group the average was just over 20 days. The average number of attendances of out-patients in all the general hospitals was 4.8 for each patient. In the teaching hospitals and also in the largest hospitals without medical schools it was just over 5 attendances. In the special hospitals, of course, this figure varies widely according to the condition treated and was highest in the orthopaedic hospitals (13 attendances).

IT CAN HAPPEN HERE

The new "Medicine" is beginning to take shape long before the appointed day provisionally fixed for April, 1948. On Dec. 11 the Council of the B.M.A. declared its opposition to the "closed shop" and is recommending to the Representative Body that "it is undesirable on principle that any practitioner should be required to join any body, B.M.A. or other." But when the Socialist State owns all the hospitals and will, therefore, be the employer of all those working in them, we shall, no doubt, see Willesden repeated on a grand scale. The Willesden incident was bad enough, but what doctors fear more than anything else is interference of the State with the responsibility of the individual doctor for his own patient. There have, of course, been the usual assurances from Government spokesmen that such a thing cannot happen here, but that it can is shown all too plainly in a letter from Dr. H. Foxell, of Birmingham, which appears elsewhere in this issue.

A patient of Dr. Foxell's suffered from cancer of the oesophagus which proved to be inoperable. A gastrostomy was performed in hospital, and as he had lost over two stones in weight the hospital dietetic expert and the consultant surgeon decided the patient should have 2 oz. of fat a day as butter or margarine. Just before discharge of the patient from hospital Dr. Foxell gave to the local food office the necessary particulars and "the medical reasons, why the extra rations are considered necessary." The local food officer granted the extra fat. Some days later Dr. Foxell received from this officer a copy of a letter from the divisional food officer of the Ministry of Food stating that the extra butter could not be continued. Dr. Foxell was informed that the medical advisers to the Ministry of Food considered there was "no need for extra butter in such cases as there is no call for a lubricant for swallowing as the operation allows the food to be inserted below the obstruction." No doubt the medical advisers to the Ministry of Food considered that Dr. Foxell and the surgeon who had done the operation were ignorant of these simple facts. Dr. Foxell, however, having the interests of his patient at heart, ignored the snub and explained in a personal letter to Dr. Edith Summerskill, Parliamentary Secretary for the Ministry of Food, that he had ordered, upon consultation with a dietetic expert, the extra fat in order to maintain the life of his patient. Dr. Summerskill, backed up by medical advisers who had not seen the patient, continued to treat at a distance, and allowed an extra 2 oz. butter *per week* "on compassionate grounds." Dr. Foxell concluded the correspondence with a letter on Nov. 29 to Dr. Edith Summerskill thus: "With reference to your letter of Nov. 18, the patient about whom I wrote died suddenly from haemorrhage a few days ago. Therefore my fight to try to prolong his life is now ended." One may be permitted to wonder what the patient in his last unhappy days thought of a State machine which deprived him of the 2 oz. of fat a day which he had been recommended in hospital. We may doubt whether he fully appreciated the humanity of the decision to allow him 2 oz. a week "on compassionate grounds."

HAEMATOLOGICAL HERESY*

BY

R. R. BOMFORD, D.M., F.R.C.P.

*Physician, London Hospital; Lately Brigadier, Consultant
Physician, 14th Army*

One of my teachers used to say that every so often there should be proclaimed a kind of sabbatical year. For this time, firm in the resolve to add nothing to medical writing, we should sift what had already been written and try to formulate principles. Whether we like it or not, the war has given some of us several such years, though I doubt if we have made the most of them; for military life, even when leisurely, is little suited to calm reflection, and libraries are often inaccessible.

A cursory acquaintance with haematological writings before the war of 1914-18 is enough to show that studies of a basic nature were interrupted by that war and some have never been resumed. A few years later the world of haematology, and indeed of medicine, was dazzled by the finding of a cure for pernicious anaemia and by the admirable experiments of the Boston school that soon afterwards revealed the source of the liver factor. I mean no disrespect whatever to the authors of these entirely brilliant discoveries when I say that their work seems in some ways to have continued to dazzle the world of haematology from that time on. It is odd, for instance, that there is, almost no mention in English medical textbooks of the artificial synthesis by Hans Fischer of a near relative of the pigment portion of haemoglobin—another event of the same period which must surely one day take its place as an achievement of the first rank; and I cannot help thinking that the theory of anaemia due to arrest of maturation in the bone marrow has enjoyed an undeserved immunity from criticism because it saw light as an explanation of one of the two or three most dramatic discoveries in medicine of the century. It is this theory that I am going to indict with such vigour as I can muster. But should this heresy, which, like many others, is only the revival of an older doctrine, one day become orthodox, I would be the first to say that the theory in its day appeared to bring order out of disorder, and did excellent service as a scaffolding on which haematological teaching could be based.

The theory of arrest of maturation as a cause of anaemia holds that, in the absence of a factor necessary for a particular stage in the ripening of red cells in the marrow, there may be an accumulation of cells which cannot develop further and a useless hyperplasia of the marrow. As one author put it, "it is as if a mass-production motor factory were unable to obtain an essential manufacturing part. Soon the assembly hall is crowded with unfinished cars, but outside the street is empty of vehicles." A simile from military life might here seem appropriate. It is as if recruits were poured into a training area but no trained troops emerge. When, however, to carry a simile a little further, it is discovered that the area is full of soldiers who have been equipped only with left-sided boots, and right-sided boots are supplied, troops pour forth into battle.

The Hopper Theory

At the height of its glory the theory of arrest of maturation (more intimately known as the "hopper theory," from the resemblance in diagrams of stored-up cells to grain in hoppers) included the liver factor, thyroxine, ascorbic acid, iron, and copper as factors necessary for different stages in the ripening of the red cell.

Thyroxine and ascorbic acid were never perhaps very strong members of the team, but they held a humble place. I like to think, though others might not agree, that some observations I made on anaemia in myxoedema (Bomford, 1938) first lost thyroxine its place. Briefly I showed that when hypothyroidism with liver deficiency and hypothyroidism with iron deficiency were excluded there remained some cases of moderate anaemia which could be cured, but very slowly, by thyroid alone, and only by this means. The blood picture in these cases resembled fairly closely that which had been produced in animals by exposing them to atmospheres richer in oxygen than the normal; and I suggested that the anaemia should be regarded as a com-

pensation—in itself physiological—to the diminished needs of the body for oxygen. Unfortunately I did not examine my patients' bone marrow, but, collecting what scanty information there was available about the bone marrow in other hypothyroid states, I suggested that the bone marrow in myxoedema was relatively hypoplastic. That this is indeed the case was confirmed a year or so later (Jones, 1940). The uncomplicated anaemia of myxoedema appears, therefore, to be a partial atrophy of the erythron (a term that has been used to indicate the blood and the bone marrow considered as a single organ) as an adaptation to the diminished need of the body for oxygen, the bone marrow is relatively hypoplastic, and there is no evidence of an arrest of maturation.

Erythropoiesis in scurvy has also been the subject of a recent paper (Israëls, 1943). The existing knowledge was again scanty, and that author writes about three cases of his own, which appear to be the first in which the marrow was examined both before and after treatment. Briefly, Israëls found that before treatment there was diminished erythropoiesis in two patients, while in the third erythropoiesis was within the range of normal. After treatment with ascorbic acid the marrow showed increased erythropoiesis in all three cases. The effect of ascorbic acid deficiency seemed to be a depression of erythropoiesis rather than a failure of maturation at any particular stage.

I do not propose to say much about anaemia due to lack of iron or copper. There is no known human anaemia due to a deficiency of copper, but there is evidence that small traces of copper sometimes assist in cure of iron-deficiency anaemia. This may well be as a catalyst in some as yet unknown stage in the formation of haemoglobin. The normoblastic hyperplasia of the marrow in iron deficiency may simply be due to the fact that this particular part of the marrow is working overtime at the production of small and ineffective cells. Since, however, iron is the only one of the so-called maturation factors which is known to be a constituent of red cells an arrest of maturation of some kind is more plausible in this instance.

The Liver Factor in Anaemia

There is left for consideration the corner-stone of the theory—anaemia due to deficiency of the liver factor. Just before the war I travelled rapidly from the West Coast of America to London. In San Francisco I heard the theory roundly criticized—it has, I think, never really taken root in Western America (Dock, 1936). In Eastern America the subject was at least a proper one for discussion, but in London I found that to question the hopper theory in pernicious anaemia was to risk being cut in the corridor or common room. So from time to time in my enforced sabbatical years I have returned to ponder on this subject.

In morbid anatomy pernicious is distinguished from other anaemias by its association with changes in the alimentary tract, particularly atrophy of the gastric mucosa; by an increase in the amount of red marrow, which is of the type known as "megaloblastic"; by haemosiderosis of the liver and other organs; and by histological evidence of active phagocytosis of red cells by the reticulo-endothelial system. It is distinguished biochemically by gastric achlorhydria, by an increase of the bilirubin in the plasma, and by an increase in the urobilinogen or similar substances excreted, mainly in the faeces. It has a characteristic blood picture, in which the number of red cells is decreased more in proportion than is the percentage of haemoglobin, and the cells are mostly large, well stained, and unduly irregular in size and shape. Finally, it is distinguished therapeutically by the fact that it is completely relieved by the injection of small quantities of the liver principle, and that the onset of the remission is accompanied by a reticulocyte response of a particular kind.

How are these various features of the disease to be interpreted? Is the anaemia due to haemolysis, for which an accelerated rate of erythropoiesis is unable to compensate, as was generally thought until the last two decades? Or is it due to a diminished rate of erythropoiesis, brought about by an arrest in the process of maturation?

Consider first the increase of bilirubin in the blood, the increased excretion of urobilinogen, the haemosiderosis, and the histological evidence of active phagocytosis of red cells. An increase in the bilirubin of the plasma used to be thought to indicate an increase in the rate of blood destruction.

* Abridged from a lecture delivered to the Poona Military Medical Society.

ut it is now regarded more as evidence of impaired liver function—of the liver's inability, that is, to deal rapidly enough with products of haemolysis. It can be neglected in this argument. The other features mentioned are regarded as indications that the rate of destruction of red cells is greater than normal in other anaemic states, and it is difficult to account for them otherwise in pernicious anaemia. Upholders of the theory of arrest of maturation usually say, therefore, that though a diminished rate of erythropoiesis is the chief cause of the anaemia, there is also present some increase in the rate of haemolysis, due to the easy breaking up of abnormal cells. But this, surely, is impossible, for simple calculation will show that the combination of a rate of erythropoiesis noticeably below normal with a rate of haemolysis noticeably above normal must lead to a rapidly progressive anaemia and an early exit.

The Part played by Haemolysis

A main argument against the haemolytic theory was that the rate of haemolysis, if the daily amount of urobilinogen excreted as in fact derived from the breakdown of haemoglobin, was so high as to be incredible. An example of an increase to thirteen times that found in health was quoted. It was therefore suggested that the urobilinogen was derived from precursors of haemoglobin, which had not been utilized because of the arrest of maturation at a stage, presumably, before the red cells acquire haemoglobin. But if it is incredible that haemolysis could be going on at thirteen times the normal rate, it is surely equally incredible that, in the presence of diminished erythropoiesis, the body should go on producing precursors of haemoglobin at thirteen times the normal rate? In point of fact, methods of estimating the daily excretion of urobilinogen in the stools and urine have improved since the time of these observations, and recent measurements show that the daily excretion in pernicious anaemia is usually not more than three or four times that in health. Such a rate of haemolysis is not incredible, and is little if at all greater than is found in other indubitably haemolytic conditions. My biochemist friends tell me that the supposition that these large quantities of urobilinogen are derived from hypothetical precursors of haemoglobin involves serious difficulties. So far as is known, urobilinogen can be derived only from the breakdown of porphyrin ring compounds, and the porphyrin ring compound of haemoglobin is formed only in developing red cells. It is difficult to see, therefore, how this increased amount of urobilinogen can be derived from anything but the breakdown of red cells, unless, indeed, it comes from some other respiratory pigment, and this seems unlikely. Further, if unused precursors of haemoglobin are excreted as urobilinogen, an increased excretion of this substance would be expected in iron-deficiency anaemia, for the response to treatment with iron suggests that there is no shortage of pigment in this disease. In fact, the excretion of urobilinogen is diminished.

The interpretation of the bone-marrow picture is linked with that of the reticulocyte response. For, according to the theory of arrest of maturation, the cells held up in the bone marrow pour into the circulation when the missing factor is supplied and give rise to the reticulocyte response. Or, to use the car factory simile, the missing part is supplied and the cars accumulated in the assembly hall pour into the street. If not this, what is the explanation of the reticulocyte response? It has been suggested by those who favour the haemolytic theory that reticulocytes, being young and tender, are more easily lysed than are mature cells. In other words, that the low count of reticulocytes before treatment is due to a selective lysis of reticulocytes. (There is a little evidence that a selective lysis of reticulocytes occurs in some forms of malaria.) When this process is brought to an end by treatment the reticulocyte count rises rapidly, and falls again slowly as matters readjust themselves. I am not sure that there is not an even simpler explanation. Let us return, admitting the fallacy of similes, to the car factory. On the haemolytic theory we must assume that the demand for cars is three or four times that which the moving belt was designed to produce. There is some acceleration, but this is not enough to supply the demand. Congestion then occurs in the early part of the assembly chain—not because the rate of production is diminished, but because cars cannot be fitted fast enough with necessary parts. When the demand falls rapidly and suddenly the moving belt, geared to the faster

rate, does not at once adjust itself to a slower rate, and pushes a number of very new cars into the street. This kind of explanation would account for the fact that there is in some cases a shower of nucleated red cells as well as an increase of reticulocytes for a short period at the beginning of treatment.

Finally there is sometimes a reticulocyte response when anaemia with malaria is treated with quinine. This must surely be due to a sudden slowing of the rate of haemolysis, and it is polemical to suggest, as I have heard done, that anaemia in malaria is due to an arrest of maturation brought about by the malign influence of malarial toxins.

Of the bone marrow I will say only that Miller and Rhoads (1934) have produced a marrow picture in animals that in essentials appeared to resemble quite closely that of pernicious anaemia. This they did by bleeding the animals regularly, separating off the haemoglobin that had been removed, and re-injecting it as a solution—a manoeuvre which reproduced some of the features of continued haemolysis.

Synthesis of Haemoglobin

Recent studies in the metabolism of pigments have possibly provided a means—though a difficult and very arduous one—of measuring biochemically and roughly quantitatively the rate of synthesis of haemoglobin (Dobriner and Rhoads, 1938, 1940). Briefly, the porphyrins of the animal body can be divided into types I or III according to whether they could theoretically be derived from types I or III of the four possible aetioporphyryns, or pattern types of porphyrin. All respiratory pigments, including haemoglobin, have a pigment portion which consists of a type III porphyrin. But normal persons excrete minute quantities of a type-I porphyrin. It has been suggested that the type I porphyrin is formed as a by-product in the synthesis of the type III porphyrins needed by the body, and thus that the amount of this pigment excreted daily provides an indication of the rate of formation of haemoglobin. The rate of excretion of type I porphyrin is increased in haemolytic jaundice, in polycythaemia vera—conditions in which no one presumably would deny that the rate of erythropoiesis also is increased—and in pernicious anaemia. So far as this work has gone it seems to confirm that erythropoiesis is accelerated in pernicious anaemia, and this finding is of course incompatible with an arrest of maturation.

Suppose for a moment that the haemolytic theory is the correct one, and see in what other ways current views about the disease would need to be modified. The conclusions of the Boston school as to the source of the liver principle and its storage in the liver would of course stand unaffected. That the liver factor was in any sense utilized in the bone marrow was never more than supposition. We should have to assume that this factor in some way prevents a particular kind of haemolysis, possibly—and there is a little evidence for this—by altering the conditions of absorption from the intestinal tract. Now the multiplication of hypothetical toxins should probably be regarded as one of the cardinal sins of medicine (and will probably, like heresy in any form, be forbidden in organized services of the future by a medical administrative instruction), but it must be admitted that a return to the older theory of a haemolytic toxin, absorbed perhaps from the intestine, might help to solve some difficulties. It would help to explain those rare cases in which the presence of a small stagnant loop of intestine—too small to be expected seriously to interfere with absorption—is associated with an anaemia of the pernicious type (Barker and Hummel, 1939). Further, if the toxin had an avidity for lipids, it might explain not only the haemolysis but the particular type of red cell found in pernicious anaemia, for the shortage in this disease would appear to be of stroma or its constituents rather than of materials necessary for the formation of haemoglobin. And, finally, a toxin with a taste for the lipids of nerve cells as well as those of red cells might help to explain the association of this anaemia with subacute combined degeneration of the spinal cord.

Conclusion

To return to more practical things; since a near relative of the pigment portion of haemoglobin has been synthesized artificially, it should not be beyond the wit of man to discover how haemoglobin is synthesized naturally and what constituents

are actually necessary for the formation of red cells. There are signs that such inquiries are being pursued actively at the present time, and advances of this kind might well open the way to much new knowledge about the workings of the erythron.

I have stated the case for a reconsideration of the part played by haemolysis in pernicious anaemia in a provocative and, some may think, tendentious manner. There is, however, a case to be considered, as was realized in America before the recent war (Minot and Castle, 1939), and my object will have been achieved if some British haematologists are induced to give their minds to it.

I am grateful to the D.M.S. in India and to Col. J. H. Baird, A.M.S., for permission to publish this lecture.

MENTAL DEFICIENCY IN NORTHERN IRELAND

A colony for mental defectives, providing ultimately for a thousand beds, within 20 or 30 miles of Belfast is recommended by the Mental Health Services Committee, whose report to the Minister of Health and Local Government is obtainable from H.M. Stationery Office (price 1s.). In a foreword the Minister (the Rt. Hon. William Grant) says: "The report gives a clear picture of the problem to be solved and contains many valuable recommendations as to the action which we in Northern Ireland might usefully take. It has been endorsed in its entirety by the Health Advisory Council. New legislation would be necessary to bring into operation a mental deficiency scheme, and this aspect of the matter is receiving consideration. I feel, however, that before the Government presents proposals to Parliament it is desirable that the committee's report should be made available to the public."

In Northern Ireland, says the report, there is no Mental Deficiency Act, no institution, no community supervision, and there is only one special school (in Belfast), which is unable to meet even local needs. Apart from the inadequate provision made by the Education Acts and the Poor Relief Acts, the responsibility for dealing with mental defectives has not been placed by statute on any authority, and for the most part these unfortunate people, estimated on the basis of parallel figures for England (Wood Committee) to number about ten thousand in the whole Province, lead a hopeless existence at in Poor Law institutions, or in mental hospitals. The problem of mental deficiency has, by years of neglect, developed a grave social evil.

Four Classes of Defectives

The committee is of opinion that the education authorities should accept responsibility only for those backward children who are educable and socially efficient, and that all mental defectives should come under the aegis of the mental deficiency authorities. "It follows, therefore, that any definitions of mental defectives for the purpose of a Mental Deficiency Act should be based on the conception of social inefficiency rather than of educational inefficiency." Mental defectiveness is defined by the committee as meaning a condition of arrested or incomplete development of mind existing before the age of 18 years, whether arising from inherent causes or induced by disease or injury. It divides mental defectives into four classes:

Class 1: Persons in whose case there exists mental defectiveness of such a degree that they are unable to guard themselves against common physical dangers.

Class 2: Persons in whose case there exists mental defectiveness which, though not amounting to that of Class 1, is yet so pronounced that they are incapable of managing themselves or their affairs or, in the case of children, will when older be incapable of doing so.

Class 3: Persons in whose case there exists mental defectiveness which, though not amounting to that of Class 2, renders them socially inefficient to such a degree that they require care, supervision, and control for their own protection or for the protection of others, and in the case of children special training also.

Class 4: Persons in whose case there exists mental defectiveness of such a nature that their behaviour is strongly antisocial and they require care, supervision, and control for the protection of others.

Ascertainment and Executive Powers

As mental deficiency is most often discovered during the school years the initial task of ascertainment will fall on the health service operating under the Education Acts. The committee recommend that where a medical practitioner is of opinion that a person is a mental defective it should be compulsory for him to notify the mental deficiency authority, with whom should rest the final responsibility of ascertaining whether there is disability of mind amounting to mental deficiency. It should be a statutory requirement that when, as a result of conducting mental tests, a teacher, educational psychologist, or school medical officer has reason to suppose that a person is a mental defective, a notification, with reports, must be sent to the mental deficiency authority to enable the case to be reviewed by the authority's psychiatrists.

The committee recommends that in Northern Ireland the Minister of Health and Local Government should be the central authority and that a regional authority should be established rather than the task of administration be thrown on the county and county borough councils. The regional authority should be composed of representatives from the county and county borough councils and other interested bodies. It should be responsible for ascertaining the provision and administration of institutions, and the supervision of defectives in the community. In addition local mental health committees should be formed to advise the regional authority and co-ordinate the activities of persons interested in the problem. The committee believes that the duties of the authorities relating to mental deficiency would be most efficiently carried out as an integral part of a general mental health service for the Province. In order to bring this about there should be either an actual amalgamation of, or the closest possible co-operation between, the mental deficiency authorities and the authorities administering all the other mental health services.

Other recommendations are that it should be permissive for a class of defectives to be submitted for treatment to the regional authority at the instance of a parent or guardian; that in an Northern Ireland legislation the mental deficiency authority should be given powers to deal compulsorily with all ascertained defectives; and it should be obligatory for appropriate care, supervision, and training to be provided; and that persons who suspect they are mental defectives should, if over 18, have the right to submit themselves for examination and appropriate treatment by the mental deficiency authority. "It is wrong to wait until the defective gets into trouble or runs foul of the law before affording him the care, supervision, and training which his mental condition requires and which it is in his own interests to receive. Mental deficiency is often hereditary, and we consider it wrong to leave any power in the hands of mentally defective parents. . . . Each case would be carefully examined by the competent authorities, and many would be allowed to remain at home or elsewhere in the community if adequate care and supervision could be provided there."

MEDICAL FOUNDATION OF EPSOM COLLEGE

The Royal Medical Foundation of Epsom College appeals to all members of the medical profession who do not already do so to subscribe to the Foundation, the object of which is to help the families of less fortunate colleagues. The Foundation in 1946 has provided more than £15,000, as follows:

50 ordinary pensions	£ 1,50
41 Foundation scholarships for boys (educated, clothed, and maintained entirely free of cost)	6,74
13 scholarships for girls	57
25 Council exhibitions for boys	1,54
138 pensions and annuities of varying amounts	3,02
Grants towards education of 51 boys and girls	1,40
Grants to widows and spinsters	33

In order to maintain this assistance the Foundation has to rely upon the generosity of subscribers and donors for over £10,000 a year. Without sufficient help from them the existing benefactions would have to be curtailed. Owing to lack of funds, many deserving applicants—medical men, widows, and children of school age—remain unassisted. The Sherma Bigg Fund enables the Foundation to make educational grants for those who cannot obtain scholarships. Donations to augment the income of this Fund would be most welcome. Subscriptions and donations for whatever aspect of the work may be sent to the Secretary, Epsom College, Surrey.

PHE NOXETOL

THE ANTI-PSYOCYANEA COMPOUND

HERE is an important new bactericide and antiseptic. Phenoxetol (Nipa) is B-phenoxyethyl-alcohol, specially purified and standardised, for use in medical treatment and for pharmaceutical preparations.

Phenoxetol is effective against certain gram-negative organisms, including *Ps. pyocyanea*. It is used by local application in the treatment of infected wounds... abscesses... indolent ulcers... associated with *Ps. pyocyanea*. It should not be used for parenteral injections.

Phenoxetol is very effective in pyocyanea infections of burns or superficial wounds. It is especially useful in the preparations of surfaces for skin grafting associated with *Ps. pyocyanea*, and may also be used together with Penicillin in solutions and creams.

getting back to PRE-WAR STANDARDS

Although this is our aim in many fields, to return to the pre-war concept of nutrition would be a grave mistake. It has now taken its rightful place as a major science that will play a large part in determining the future health of nations.

One main advance is the realisation that, whether prepared communally or in the home, all meals should be carefully planned to ensure a good balance between energy-giving and protective foods.

Marmite is often included in planned meals, as it provides in a pleasant and convenient form essential vitamins of the B₂ group, which have a definite protective value.

MARMITE

yeast extract

contains

Rubeflavin (vitamin B₂) 1.5 mg. per oz.
Niacin (nicotinic acid) 16.5 mg. per oz.

Jars: 1-oz. Bd., 2-oz. 1/1, 4-oz. 2/-, 8-oz. 3/3, 16-oz. 5/9

Obtainable from Chemists and Grocers
Special terms for packs for hospitals and welfare centres

Controlling the asthmatic spasm

In asthma and other allergic disorders no treatment for the attack has yet disturbed the pre-eminence of adrenaline, the physiologically specific, natural inhibitor of those disorders; but, when the attacks are frequent and of considerable duration, the use of the hydrochloride has the disadvantage of making frequent injections necessary, owing to its relatively transient effect.

With the introduction of **Hyperduric ADRENALINE** this troublesome frequency of injection has been overcome by the combination of the active base with mucic acid (the distinctive feature of the Hyperduric series) and the action of the resulting adrenaline mucate is observable for 8 to 10 hours.

PROLONGED CONTACT
antiseptic

During a systematic investigation into the antibacterial activity of the monoaminoacridines, 5-aminoacridine emerged as a antiseptic having properties similar to those of proflavine 'Flavogel' (5-aminoacridine) is the Glaxo preparation of this potent antiseptic in a water-miscible jelly base for use on cuts, wounds and protective dressings, etc. 'Flavogel' is valuable also as an antiseptic lubricant for catheters, cystoscopes, an specula, and in ante-natal examinations. 'Flavogel' has powerful antibacterial activity, is effective in the presence of serum and is prolonged in action. The consistency of the jelly base maintains the antiseptic in contact with the tissue enabling it to exert the maximum antibacterial effect. 'Flavogel' is ready for application direct from the tube. It is convenient to carry, clean to use and does not stain skin or clothing.

'Acramine' (5-Aminoacridine) is available also as a powder for making up solutions.

FLAVOGEL

5-Aminoacridine Hydrochloride in water soluble jelly base. 1-oz. tubes and 9-oz. jar.

IF A CHILD
MUST HAVE AN
HYPNOTIC THE
DRUG OF CHOICE IS

"ISOBROM"

She is physically well, but still she does not sleep. The "sleep habit" is lost.

The answer is not the slow-acting barbiturates, with the risk of drowsiness the next day, or bromides with the danger of skin rashes.

"The answer is 'ISOBROM.'" It acts quickly, and the sleep habit is soon restored. Its action is all over by the morning, leaving the child bright and alert after a good night's sleep.

"ISOBROM"—a combination of bromisovalerylurea and carbromal—is a reliable sedative and mild hypnotic. It can be used for long periods without hepatic or renal impairment, damage to the central nervous system, or risk of skin rashes, and will not produce any after-effects.

THERE ARE NO KNOWN CONTRAINDICATIONS

ACTION: "ISOBROM" induces sleep usually in less than half an hour. The effect lasts 4-5 hours and is usually followed by natural sleep.

In bottles containing 25, 100, 250 and 500 tablets.

This preparation is not advertised to the public.

SYNTHETIC INSECTICIDES IN THE TROPICS

A team of three entomologists, two chemists, two field officers, and a laboratory technician have been making experiments, under the direction of the Colonial Office, on the effectiveness of synthetic insecticides—D.D.T. and gammexane—in the control of insect pests in East Africa, and results were reported by Dr. C. B. Symes, Senior Medical Entomologist, Kenya, on Dec. 10.

In 1944 the Colonial Office was able to obtain sufficient D.D.T. for an experiment on a reasonable scale in malaria control in Kenya. Solutions were applied to the interior wooden surfaces of houses, with promising results considering the small scale of the experiment. In 1945 the team was formed, and certain areas of vegetation were selected in Uganda, including isolated islands and headlands of Lake Victoria, for a full-scale experiment in combating the tsetse fly and the malaria parasite. In fighting the tsetse fly two areas, one of 40 and the other of 100 acres (0.16 and 0.40 sq. km.), were taken and the bush was treated in the one case with D.D.T. and in the other with gammexane. The fly populations in these areas were measured, and small portions selected where the flies appeared to be in greatest number. The actual intensive spraying was carried out over 2 to 4 acres (8,000 to 16,000 sq. m.) of jungle. After a single application of either D.D.T. or gammexane the fly population was found to have diminished by about 50%, and on a further application of gammexane in double the amount the decrease was carried to 80%. The substances were found to be having little effect a week after application, owing partly to the fact that the insecticide was applied in an oily solution which was readily absorbed by the leaves and stems of the vegetation and partly to the prolonged sunshine, which broke down the power of insecticides after a certain time. It was not possible to bring about complete disappearance of the insects by a single application.

The effect of repeated applications on the same patch of vegetation was tried over a period of fifty or sixty days—significant because of the approximately fifty-day life-cycle of the tsetse fly. The fly population was reduced by about 99% in one such experiment, but a later experiment was vitiated by natives who brought herds of cattle to the experimental regions, and thus linked up those regions with an untreated area. The question arises of economy in treatment of large areas of vegetation. One plan would be to distribute the insecticide by aeroplane, but unless there is some means of lateral dispersion this would touch only the top layers. Another possibility is the use of smokes, but then there is the difficulty of changing winds.

Control of Insect Vectors

Six of seven native sub-districts in rural Uganda were sprayed with synthetic insecticides, the seventh being used as a control. These experiments, generally speaking, indicated that oily solutions of both D.D.T. and gammexane proved effective in Uganda in stopping the rising seasonal incidence of malaria in the rural population. But such solutions were largely lost by absorption in the mud walls of native houses. A solution of gammexane powder mixed in water and applied with a sprayer was tried, and reduced the "malaria parasite-rate" in the area by one-half in three months. The powder in water was not taken in by the absorbent surfaces to anything like the same extent as a straight solution in oil, and it is hoped that dispersible powders will prove of value in malaria control. Experiments by various investigators in different parts of the world do not all accord with the Uganda experience. Some have found the preventive use of D.D.T. solutions against malaria to be of no particular advantage, while others have made sweeping statements as to the efficacy of the method. The Uganda operations certainly seem promising, but, of course, they require critical examination. In some other places the observations have been confined to the effect on mosquitoes, but in Uganda the malaria itself has been measured and it is in the "malaria rate" that the most striking results are shown.

The work is being extended by investigators in tropical Africa who are applying these synthetic insecticides to the control of various major pests and disease vectors. In Kenya some promising results have been obtained with the use of

D.D.T. in the control of *Simulium ochraceum*, a small fly which breeds in running water and causes oncocercosis, a serious problem in parts of Kenya and elsewhere. It is an advantage that this work is being done under the aegis of the Colonial Office and financed centrally, instead of being undertaken by the individual governments; there is more likelihood of consistent and large-scale results being obtained. It is the general feeling of the Colonial Office authorities that special research teams are well worth while.

No attempt has been made to evaluate the relative merits of D.D.T. and gammexane. Gammexane used against insects has a more rapid effect than D.D.T., but it is more volatile and likely to be lost. New and improved insecticides may well appear, and when the best manner of using them is worked out it is quite possible that they may revolutionize life in the Tropics.

TUBERCULOSIS ALLOWANCES

A deputation from the Joint Tuberculosis Council (*Journal*, Dec. 21, p. 955), supported by additional representatives of associated organizations, of the Hospital Almoners' Association, and the Tuberculosis Care Workers' Association, waited on the Ministry of Health on Nov. 15, 1946. The deputation was received by Sir Arthur Rucker, with Sir Wilson Jameson in the chair. Representatives of the Ministry of National Insurance, the Assistance Board, the Department of Health for Scotland, and other officers of the Ministry of Health were also present.

For the Ministry it was explained that it fully accepts the view that tuberculosis calls for special provision in the interests both of the patient and of public health, but that this provision in future would have to be made within the general pattern of the new social legislation. The new National Insurance Act would provide benefits in various adversities on a scale that it was hoped would, in general, be adequate in itself. There would be those, however, who would need something more, and this would be forthcoming under a National Assistance Bill which was now in preparation to sweep away the Poor Law and to give effect to a new concept of Government assistance for those in need. Tuberculosis patients would be basically provided for in this way, conforming with the general pattern of social security. But, by virtue of their special needs, the Assistance Board would, it was hoped, be empowered in the new Bill to make payments to needful persons under treatment for pulmonary, but not for non-pulmonary, tuberculosis on a scale higher than the normal scale of assistance applicable to the community as a whole.

The Ministry took note of criticism regarding the deduction of family allowances from payments under the present tuberculosis scheme, and the alleged inadequacy of the general scale-rates under this scheme. Increased rates of allowances are now to be made for dependants under 16 years of age. (*Supplement*, Dec. 21, p. 162.)

The Nuffield Provincial Hospitals Trust is advised by a Scottish Committee on matters relating to hospital or ancillary services in Scotland. The trust has a medical committee which has lately issued a second interim report, presenting as appendices memoranda which have been submitted to it during the last two or three years on a health service for university students, the care of the chronic sick and the aged and infirm, standards of hospital services, the place of the hospital almoner in the regional health scheme, and a report on the health and sickness records bureau in Glasgow. This last report is a condensation of the full account of the incidence of acute perforated peptic ulcer in the West of Scotland (*British Medical Journal*, 1944, 2, 617, 655).

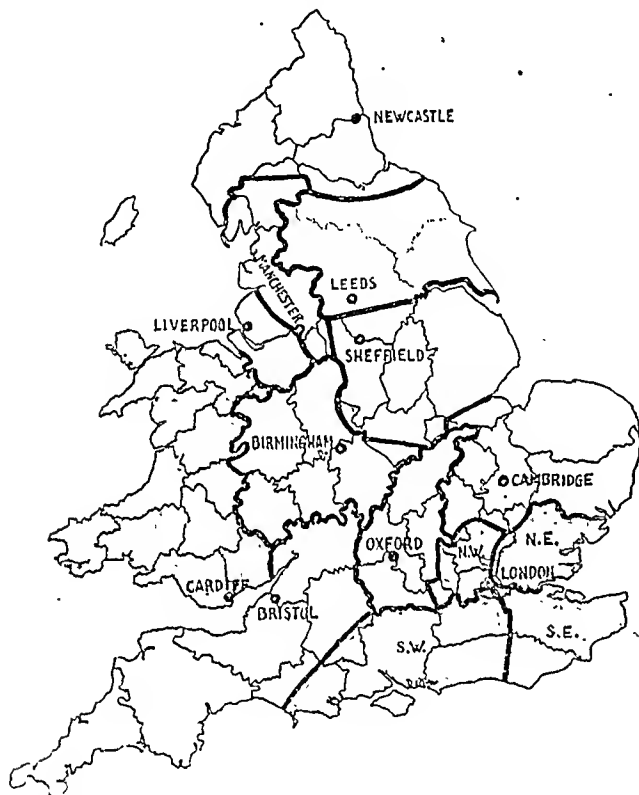

Dr. A. Grieg Anderson, who is chairman of the Medical Committee, in a report on a health service for university students brings forward a draft scheme for medical examinations for Aberdeen students by a whole-time medical officer who is soon to be appointed. Dr. Duncan Leys suggests that all medical staff at a hospital above the rank of registrar might have a definite obligation to consult without fee in patients' homes at the request of any doctor in practice in the area, unless their terms of appointment specially recognize this to be impracticable. Sir Alexander Macgregor and Dr. Crawford Knox write useful memoranda on the standards for nursing staff in hospitals.

AREAS OF REGIONAL HOSPITAL BOARDS

THE FIRST STEP

As the first step towards setting up the administrative machinery for the future hospital service, the Minister of Health (Mr. Aneurin Bevan) on Dec. 20 laid before Parliament an order defining the areas for which Regional Hospital Boards will be responsible under the National Health Service Act.

On Nov. 15 the Minister sent out to all the bodies concerned—over 200 in all—provisional proposals for the boundaries of these areas (*Journal*, Nov. 30, p. 828), and asked for their views and advice. Among the bodies from which the Minister has received observations are the universities and medical schools, the British Hospitals Association and its area committees, the

three Royal Colleges, the King Edward's Hospital Fund for London, the Nuffield Provincial Hospitals Trust, and the local health authorities (county and county borough councils). In light of these views he has made a number of modifications, which the following are the more important:

1. Wigan and district and Crewe and district are associated with Manchester instead of with Liverpool. [Note.—Representations have been made that the area of the Liverpool region is inadequate to meet the needs of a large medical school and modern teaching hospital. The force of this contention is realized, and the needs of the Liverpool region have been kept in mind throughout. It is felt, however, that they can best be met by administrative arrangements rather than by varying the regional boundaries, which would create other difficulties. There has long been a close link between the Liverpool hospitals and North Wales, and this will be preserved by providing representation for Liverpool representatives on the Welsh Regional Board. Similarly there are links between Liverpool and North Lancashire which will be maintained by appointing for that area a subcommittee of the Manchester Regional Board on which Liverpool representatives will sit.]

2. Goole and neighbourhood are associated with Leeds instead of Sheffield.

3. Burton-on-Trent and neighbourhood are associated with Birmingham instead of Sheffield.

4. Hineley is associated with Sheffield instead of Birmingham.

5. The whole of Bedfordshire is associated with London instead of the northern part being associated with Cambridge.

6. High Wycombe and district are associated with Oxford instead of London.

7. West Dorset (except Lyme Regis) is associated with London instead of Bristol.

8. North-east Gloucestershire and North-east Wiltshire (including Swindon) are associated with Oxford instead of Bristol. Details of the regional areas are given in the Order, which is: No. 2158.—The National Health Service (Determination of Regional Hospital Areas) Order, 1946, dated Dec. 18, 1946, made by the Minister of Health under section 11 of the National Health Service Act, 1946 (9 and 10 Geo. 6. c. 81).

Reports of Societies

PROBLEMS OF RENAL LITHIASIS

In the Section of Urology of the Royal Society of Medicine on Nov. 28 Mr. R. H. O. B. ROBINSON, the new president, delivered his address on "Problems bearing on the Aetiology, Diagnosis, and Treatment of Stone in the Upper Urinary Tract."

Relationship of Infection to Stone

Organisms in the urine in the pelvis of the kidney might change from time to time, and this suggested that its composition varied considerably, and that organisms absorbed from the bowel and then excreted might, or might not, find conditions favourable to their growth.

Calculi associated with hyperparathyroidism were a well-recognized group at the present time, but a point not so well appreciated was that they could occur without any lesions of the bony skeleton. Deficiency of vitamin A disturbed the calcium-phosphate ratio and produced changes in the epithelium of the urinary tract. Stones found in such circumstances were of Randall's type 2, starting as tubular inspissation of calcium phosphate, but after prolonged vitamin deficiency severe tubular changes occurred. In patients suffering from peptic ulcer, calculus was attributable to the high intake of milk, alkalis, and calcium carbonate, with a resultant alkaline urine, but few statistics were available.

Calcium-phosphorus metabolism was probably the most important factor in stone formation, as calcium figured in all types of stone under discussion. The metabolism of citric acid had a definite relationship to the formation of renal calculi. Oestrogens increased the citrate excretion in the urine and lowered that of the calcium. The addition of citrate would prevent precipitation of calcium phosphate from solution, and this effect was maximal in alkaline solution, in which calcium phosphate was least soluble. This was obviously an ideal mechanism for the kidney to prevent precipitation of calcium phosphate; a further step in prevention would be a reduction of the phosphate ions, and this could be brought about by the administration of aluminium hydroxide gel, which formed a highly insoluble aluminium phosphate in the gut, thus reducing the absorption of phosphorus.

Treatment of Calculi

The indications for active surgical intervention were obstruction of the drainage mechanism of the kidney, as evidenced by intravenous pyelography. Non-operative treatment was indicated under the following conditions: (1) Limitation of the calculi to the cortical part of the kidney, where they had no macroscopic connexion with a calix; (2) mobile stones not causing obstruction and of such a size as to make passage *per vias naturales* possible; (3) stones composed of calcium phosphate or mixed phosphatic stones; (4) bilateral stones, associated with gross disease and limited function in both kidneys, rendering any operation hazardous.

Much could be done by forced fluids, by correction of faulty diet, and by attempts to control superadded infection. Postural drainage might be very helpful in dislodging a stone. In the case of decubitus calculi or phosphate stones attempts

might be made at solution with Suby's G fluid used before secondary infection, particularly with urea-splitting organisms, supervened.

In the operative approach to the kidney, incision in the line of the twelfth rib, with subperiosteal resection of the rib, was favoured. Calculi should preferably be removed by pyelolithotomy, and with a proper exposure and suitably curved forceps the calices could be entered and stones removed from the pelvic incision. Incision in the long axis of the ureter with suture, if haemostasis was complete, was preferred unless the pelvis was thickened and friable. Nephrolithotomy was an undesirable operation.

The indication for active surgical intervention was dilatation of the upper urinary tract above the stone, particularly if infection was superadded. If neither dilatation nor infection was present a conservative attitude could be adopted indefinitely. Impaction of ureteric calculi commonly occurred between second and third lumbar vertebrae, or on the pelvic floor in the terminal part of the ureter.

THE PROBLEM OF TONSILLECTOMY

At a meeting of the Liverpool Medical Institution, on Nov. 21, with the president, Dr. G. F. RAWDON SMITH, in the chair, Mr. T. B. LAYTON opened a discussion on the responsibility of the physician in the problem of tonsillectomy.

Mr. Layton said that this operation was carried out too often and for indications which did not bear close scientific inquiry. The physicians referred patients for tonsillectomy with the idea of removing the focus of sepsis, and if after full investigation they expressed the view that the tonsils were at fault, this was difficult for the surgeon to refute. He outlined the indications for the operation and drew attention to the danger of operating during the winter months and epidemic periods. It was only streptococcal infections of the tonsil which gave rise to trouble.

In the discussion which followed, Dr. G. F. RAWDON SMITH emphasized that the size of tonsils and amount of adenoid tissue removed at operation had lessened considerably during the past twenty-five years. Dr. R. W. BROOKFIELD referred to the difficulty of determining whether the tonsils were at fault. Two attacks of tonsillitis in one year with persistent rheumatic pains justified tonsillectomy, and was often a prelude to complete resolution in those cases of acute nephritis which had continuing albuminuria and haematuria.

Mr. HORACE MATHER considered that the general practitioner and the mother should be adequately consulted before tonsillectomy was undertaken in children. Dr. W. GRANT MCAFEE inquired about the indications for the removal of tonsils in the diphtheria carrier. Mr. R. J. MARTIN raised the question of the school child with constant colds referred for the operation. Probably tonsils and adenoids were responsible for a small proportion of these cases, and tonsillectomy was only indicated in recurring attacks of tonsillitis or in gross obstruction. Dr. C. A. CLARKE pointed out the danger of removing children's tonsils when there was an epidemic of anterior poliomyelitis. In Australia a statistically significant number of cases of this disease had occurred in children who had recently had their tonsils removed.

A British Council for Spastic Paralysis was constituted at a London meeting on Dec. 12, under the chairmanship of Prof. J. M. Mackintosh. There are thousands of children and adults suffering from this disability in Great Britain, and the main object of the new council will be to encourage and organize research into the best means of education and treatment and to provide adequate school, hospital, and other facilities. The new council is widely representative and has been assured the active support of the Ministry of Education, the Ministry of Labour and National Service, the Ministry of Health, the Ministry of Pensions, the Scottish Education Department, and the Department of Health for Scotland. A constitution has been adopted covering a wide range of objects, including discovery and registration of cases, establishment of special day and residential schools, clinics, and vocational training. There is one small teaching unit already in existence, and promise of establishment of special schools for children suffering from this disability near Croydon, Birmingham, and Plymouth.

Correspondence

A Foretaste of Control?

STR.—Early in October a patient of mine suffering from carcinoma of the oesophagus was discharged from hospital. He had had a gastrostomy carried out, an exploratory thoracotomy having shown the growth to be irremovable. He had lost over 2 stones (12.6 kg.) in weight, and the hospital dietetic expert, in agreement with the consulting surgeon, decided it was necessary for the patient to have 2 oz. (60 g.) of fat a day in the form of butter or margarine. He was given this in hospital in addition to 2 pints (1.1 litre) of milk a day and other substances that would pass through the gastrostomy tube.

When he was about to be discharged I wrote to the local food office (in accordance with Form MED. 1, p. 7) "a detailed medical statement, giving full particulars of the applicant's condition and the medical reasons why the extra rations are considered necessary." As the result of this confidential report the local food executive officer granted the extra fat. Some days later this officer sent me a copy of a letter from the divisional food officer of the Ministry of Food, dated Oct. 14, 1946, and signed by the a/assistant divisional food officer:

"I have now received a reply from Headquarters that our medical advisers are of the opinion that in cases of gastrostomy the important point in relation to food is that the food chosen is such that will go through the gastrostomy tubes. In their opinion there is no need for extra butter in such cases as there is no call for a lubricant for swallowing as the operation allows the food to be inserted below the obstruction.

"It is their opinion that in these cases, however, it would be advisable to permit a priority allowance of two pints of milk and eggs at the rate of three per week, and perhaps in this case the doctor will be satisfied if the extra allowances are granted.

"I shall be glad, therefore, if you will point out to the doctor the allowances recommended by our advisers, giving the reason why they are not prepared to recommend extra butter. Medical report is returned herewith."

In response to this communication I wrote a personal letter to Dr. Edith Summerskill "as a doctor" (a favourite expression of hers), as I felt it was wrong to reduce my patient's fat ration—he was only just holding his own in weight. I pointed out that my patient was not ordered butter "as a lubricant for swallowing" but as a means of feeding him with extra fat, as considered necessary by the hospital dietetic expert; also, that the Ministry had entirely missed the point that the extra fat was necessary to help to maintain life. I further commented that the Ministry's medical advisers could not fully understand the case, not having seen the patient. It was not until nearly three weeks later that I received a letter dated Nov. 18, 1946, from Dr. Summerskill's private secretary:

"Dr. Summerskill has asked me to reply to your letter of Oct. 30 recommending an extra allowance of butter for one of your patients.

"The refusal of the extra allowance by our local office was fully in accordance with the recommendations of our medical advisers. Dr. Summerskill feels, however, that this is a case where an extra 2 oz. of butter per week should be allowed on compassionate grounds."

"Compassionate grounds" indeed! So the patient was to be allowed to have less than what was considered necessary for life. The necessity of maintaining life was apparently dismissed and the patient was to be allowed, "on compassionate grounds," to go downhill by the recommendation of the medical advisers to the Ministry. The end came, and I wrote on Nov. 29:

"With reference to your letter of Nov. 18, the patient about whom I wrote died suddenly from haemorrhage a few days ago. Therefore my fight to try to prolong his life is now ended."

I pointed out that it seemed wrong that the opinion of a general practitioner of very considerable experience—especially when supported by a distinguished consulting surgeon and a recognized dietetic expert—should be overruled by the medical advisers to the Ministry who had never seen the patient. Is this a foretaste of control?

And now it is all over, a question comes to mind. Recently the G.M.C. struck off the *Register* a doctor who had given panel certificates without seeing the patient. What might well

be asked is the position of medical advisers at the Ministry who, without seeing the patient, advise against the opinion of the doctors in charge of the case.—I am, etc.,

Birmingham.

HUMPHREY FOXELL.

National Health Service Act

SIR,—It was a tragic day for medicine when it became a political issue, but for this the profession is not responsible. As many doctors have not had the time to read the Act or the full account of the debates during its passage through both Houses of Parliament, it is well that we should be told that the doctor is "first a citizen." This apparently harmless statement can mean nothing less than that a doctor must submit his clinical judgment as to what is best for his patient to the overriding authority (or duties) imposed by bureaucracy in the name of the people. Many German doctors are now being sentenced for criminal offences committed by order of their government for the alleged welfare of the people. It is also well that the Willesden Borough Council should have let the cat out of the bag, thereby eliciting a gentle rebuke from the Minister for not having the taste and good sense to wait a little longer. It should now be plain to all what is going to happen in a year or two, when there will be only one employer.

We can respect the sincerity of those who, through fanatical adherence to a group, large or small, lose their powers alike of clear thinking, detached observation, and foresight, but for the rest of us there can no longer be any doubt of a quickening pace of totalitarianism, both precept and practice, in central and local government in this country. Persecution of opposing minorities is spreading rapidly, and even freedom of conscience is looked upon askance.

Apologists for the Act claim that its remaining defects are but minor matters, but can we accept this description as apt for the clauses (retained owing to the refusal of the Minister to accept amendments pressed by our professional representatives in and passed by the House of Lords) that permit the Minister to refuse submission of the Central Health Services Council's report to Parliament, and deny the right of appeal to the courts by an aggrieved practitioner? It is further claimed that the doctors have no right to decline to co-operate in the application of the Act, more particularly as they do not yet know how it is to operate. The answer to this is that Parliament did not hesitate to pass an Act the ultimate implications of which it knew nothing. The Minister was handed a blank cheque. If the doctors enter into discussions on such a basis they will be held jointly responsible for the outcome, although there is no reason to suppose that the Minister will take any more notice of their views at this stage than during the passage of the Act through both Houses. If we then protest and try to withdraw, the Minister can accuse us of entering freely and willingly into discussion, and then, out of mulish obstinacy, trying to sabotage the scheme sanctioned by Parliament and handed by the nation.

The issue is surely clear. The Act is a bad Act, inimical to welfare of the patient and endangering the freedom of the doctor to serve his patients as he sees fit. Let the doctors make this plain and leave it to the Minister to frame his regulations and take full and sole responsibility for the Service. Those doctors who then feel they can enter it with a clear conscience will do so. We must make no mistake about it. The writing on the wall at Willesden, and in the denial to the doctors of the elementary right of all citizens—appeal to the courts—is there for all to see. There can be no doubt that this is a moral and ethical issue of the first importance. The temptation to sell our birthright for a mythical security will be strong for many, but for those who succumb there will be no turning back, no second chance.—I am, etc.,

London, W.1.

ALAN MABERLY.

SIR,—Dr. H. B. O. Cardew's letter (Dec. 7, p. 873) needs to be related to its setting. I have no real fear that its substance will influence any members of the profession, but one has recently encountered several muddled and vacillating minds. Dr. Cardew contested Weston-super-Mare in the General Election and is now, I believe, prospective Socialist candidate for a local constituency. I think it may justly be said that his ambition is political rather than professional.

Most of his plausible statements can be refuted. We are not fighting this Act for political motives. The profession has had a raw deal from all political parties, and the last direct (and successful) fight was with a Conservative Minister in 1923. It is true that the B.M.A. has for many years urged a comprehensive health service, confirmed by the profession in 1944, and that the electorate probably approve the idea, but the majority of the profession cannot, and I am certain that the majority of the thinking electorate will not, approve the National Health Service Act—a polycephalic, trichotomous monster, even armed with the traditional spiked club. The Minister has built for us, without "meeting us doctors in a reasonable spirit," a cumbrous and forbidding barracks, detention cells, kettledrum, and all. And now, says he, will you come into my parlour and discuss decorations, furnishings, and pieces of silver?

The B.M.A. runs on thoroughly democratic lines, and the Council have the duty of implementing the decisions of the meetings of representatives. Four representatives of the Services are elected annually to Council. The "tens of thousands of members" (total membership 52,500) have only themselves to blame if the local committees, Divisional representatives, and members of Council, for whom they did not trouble to vote, may not always represent their wishes. Failure of the democratic intention can occur owing to inertia or ignorance of the *demos*. And it is precisely for that reason that the A.R.M. last July asked for a plebiscite of the whole profession, including those on active service. Can anything be attempted more democratic than this?

Doubtless Dr. Cardew will be able to blind himself to these things so that he may continue faithfully to toe the party line and to use the profession and Association of which he is a member as fodder for his political platforms. Political motives many of us may have, but it is quite clear where the political beams are.—I am, etc.,

Bristol.

A. GORDON HERON.

SIR,—Dr. Lennox Johnston in his letter (Dec. 7, p. 874) says: "The 'fundamental principles' on which the B.M.A. has taken its stand are not moral principles. They are merely political. . . ." It is hard, however, to understand how politics can be kept out when discussing an Act of such grave significance not only to our profession but to the whole community. Political views are in the main based on moral principles—some no doubt of a higher and some of a lower variety. I trust, however, that Dr. Johnston does not think that the higher standard is only the possession of those who believe in the Socialist doctrines. Conservatives believe in private enterprise and consider that the natural rewards that fall to industry, ability, and foresight have a high moral value. They see nothing wrong with private ownership and private profit honestly come by, and they consider that brisk competition is the best way, at the present stage of human development, to secure good service.

Doctors who hold these views must feel that the National Health Service Act as at present framed is likely to be harmful, and it is their duty to resist it by all fair and lawful means; and further, that to enter into negotiations about the details with a Minister who refuses to consider alteration in the fundamental principles can only be futile, and would give the impression to the public that we agreed with these principles. To give way now because we fear we would suffer in a struggle with the Government, as suggested by Dr. Johnston in his last sentence, is advice difficult to reconcile with his previous insistence on moral principles. If there are not sufficient doctors available the Act must be unworkable, and medical service will have to continue as at present until the basic principles of the new Act are made more acceptable. There is no question of any illegal action nor of a doctors' strike—both points which ought to be made very clear—I am, etc.,

Wakefield.

D. H. RUSSELL.

SIR,—The vital importance of the subject impels me to comment on some of the letters in the *Journal* of Dec. 7. Mr. W. Etherington-Wilson and others (p. 874) have realized that this matter is not merely a small sectarian one affecting the doctors alone but a threat to the very liberty of a section of the British people and an utter negation of all we have fought for in two

terrible wars. Some of us seem to have become so confused as to think that a "No" in the plebiscite indicates a vote against a National Health Service; that of course is nonsense. What we object to is an Act which has been ruthlessly imposed on us, not only without reasonable consultation on its terms, but in wilful opposition to certain principles which the Government knew well we held dear and would fight for—a method now popularly known as the "dictatorship of the proletariat."

Dr. H. B. O. Cardew (p. 873) talks of a "clear mandate from the people." Nonsense! The "people" were not a majority of the community, and the vast bulk of them knew nothing and still do) and cared less about a National Health Service, except that it was "something for nothing" (they were not to hold the cost) and only one plank in the Utopian platform on which the workers were to sit at ease while the good things of life appeared by magic. Even if the Government had had a clear mandate it was not a mandate to impose terms which were an outrage on the liberty of the subject and which cannot be put into effect, as only we seem to realize, to the ultimate disadvantage of the most important person of all—the patient.

Dr. Lennox Johnston (p. 874) admits in his final sentence that the Minister has called his bluff at least; he disguises only with a paean of praise for the principles of Socialist society that it is his own welfare which is his main concern. He does not blame him for thinking of that; we are all concerned for our livelihood; but we can at least fight for it, and we are not yet means at the last ditch yet.

I have voted against negotiation because we have had sufficient experience of the present Minister's conception of the word and his own denial of it to know that it would be a farce unless backed by a strength equal to his own; and also, so far as I can see, any terms negotiated might well be only temporary as they could afterwards be altered by a stroke of the Ministerial pen. Before we can honestly negotiate terms we must have the Act so amended as to restore our liberty if we join the Service, and it would appear that we must impress on the Government that we have not fought and won a war against dictatorship only to submit to it disguised as democracy of the Soviet pattern.—I am, etc.,

FitzWilliam.

J. S. LAURIE.

SIR,—At a time when medical men are threatened with the loss of the goodwill of their practices and hospital governors are in danger of losing their hospitals, the following quotation from Plato's *Republic* seems very apposite.

"This form is a despotism, which proceeds not by small degrees but by wholesale in its open or fraudulent appropriation of the property of others, whether it be sacred or profane, public or private: perpetrating offences, which if a person commits in detail and is found out, he becomes liable to a penalty and incurs deep disgrace; for partial offenders in this class of crimes are called sacrilegious, men-stealers, burglars, thieves, and robbers. But when a man not only seizes the property of his fellow-citizens but captures and enslaves their persons also, instead of those dishonourable titles he is called happy and highly favoured, not only by the men of his own city but also by all others who hear of the comprehensive injustice which he has wrought."

It should also be remarked that Plato forecast the successive forms that government may take: aristocracy, then its overthrow by oligarchy, and its overthrow by democracy. According to Plato democracy inevitably paves the way for tyranny, the future tyrant being at first the selected champion of the commonalty but gradually becoming more and more powerful, obtaining increasing authority under specious pretences and finally turning out a consummate tyrant. Has not this prince of ancient philosophers a message for the medical profession (and, indeed, the whole community) to-day?—I am, etc.,

Weston-super-Mare.

CYRIL G. EASTWOOD.

SIR,—Surely the first and most essential points for the honour and prestige of our profession are that the customs and usages, including the right of private practice and the buying and selling of such, shall be forcibly insisted on and clearly agreed to by the Minister of Health before any further talk, and, if refused, any further discussion be promptly broken off and bluntly refused. No recently qualified man should bear any pecuniary loss, as the B.M.A. has ample funds and he will be well supported.

I suggest that the excellent letter on the plebiscite (Nov. 9, p. 707) written by our former highly respected Secretary, Dr. Alfred Cox, be carefully reread.—I am, etc.,

Birmingham.

E. T. LARKAM.

SIR,—I suggest that a brief and explicit statement be made to the Minister of Health and to the lay Press that the medical profession is not only willing but desirous to co-operate in working a good National Health Service Act, but it refuses to work a bad one. Doctors are best qualified to judge whether the Act is good or bad, and they have decided that the present Act is a bad one. Many words give rise to confusion of thought.—I am, etc.,

Cheltenham

J. RUPERT COLLINS.

Willesden and the Plebiscite

SIR,—I wonder if the word "Willesden" will make those who answered "Yes" think again and write and say they should have answered "No." Willesden, I think, has shown what we may expect if we put our heads in the noose. I cannot help feeling that the B.M.A. did not put the case clearly.

Our representatives decided that the medical profession demanded among other things (a) no direction; (b) no basic salary, (c) sale and purchase of practices to continue. If we are going to insist on these it is useless to negotiate. Neither Mr. Bevan nor the B.M.A. can negotiate on these principles. They are passed into law, and that leaves the position as follows: If we insist on sticking to those three and any other essential demands, get the Act altered allowing our demands, and we will be only too willing then to negotiate on Regulations.—I am, etc.,

Leicester.

FILMER COLEMAN.

SIR,—It is quite clear that the Willesden incident has fundamentally altered and clarified the relationship between the medical profession and the Ministry of Health. Why not register this? There should be another plebiscite: "Are you willing to work as a Civil Servant under the Ministry of Health?" There would be an astonishing response to this. The B.M.A. should be active, not passive, for the time is now very short.—I am, etc.,

Old Colwyn.

A. NORMAN LEEMING,
Late President, N. Wales Branch, B.M.A.

SIR,—First, "No" by a considerable majority of general practitioners; then a unanimous and resounding "No" by the Willesden doctors and nurses. I cannot doubt that if the Willesden "No" had been recorded before the plebiscite, there would have been not a considerable but a nearly unanimous "No" by the general practitioners. All who are not made blind by doctrinaire dope can now see the prematurely disclosed Socialist threat—a mental concentration camp for the profession.

I am the youngest practitioner in this area. I do not belong to any political party, but when I see a party endeavouring to make my profession a totalitarian tool I know I doubt the integrity of that party in spite of its professed ideals.

We must indeed close our ranks and agree to negotiate only with prior Government assent to the Principles so ably enunciated by our Negotiating Committee—this assent being secured by Act of Parliament. While we are prepared to take our part in a health service for the nation, we are not willing to prostitute our ideals for the sterile security now offered to us. Let us therefore say "No" with growing voice until our Principles are conceded to us.—I am, etc.,

Teignmouth.

GEORGE A. F. QUINNELL.

Trade Union for Doctors

SIR,—I am an ardent believer in the preservation of all individual liberties that do not directly conflict with the good of the community and dislike the dictatorial attitude of the Willesden Borough Council and the whole idea of the "closed shop." At the same time it is not necessary for us to form a really effective trade union now that the N.H.S. Bill has become law?—I am, etc.,

London, W.14.

C. W. ROE.

The Plebiscite

SIR,—I agree with several of your correspondents that the plebiscite paper was too lengthy and difficult to understand. Many believed that if they replied "No" they jeopardized their future opportunities for work in any hospital, such being at the disposition of a Minister who has not shown understanding of the personal relationship of doctor and patient. His attitude of "abhorrence" of what seems to us normal and right proves his ignorance of our profession. As a matter of fact even many of the public mistakenly believe that when a practice has been sold they are obliged to summon the new doctor who has bought the practice. They do not know that they have a right to go to any doctor whom they prefer. Possibly Mr. Bevan has the same misapprehension, which would explain his "abhorrence" of the sale. In reality a sale implies that a suitable successor is likely to follow; and that he is introduced to the patients, with complete notes of their maladies and of the important matters in their family history.

Here is the true history of a case which would have suffered sadly under Mr. Bevan's dictatorship. An elderly physician, full of wisdom, contracted tuberculosis from a patient and was slowly dying. He had a large family, and was in despair as to their future, as he had been a bad business man and could have left no money for the children's education. He saw several young men who were keen to buy his large practice; he selected the one most suitable and for a whole year was able to pass on to him his experience and his wisdom. The young man was grateful and soon able to redeem his debt for the purchase of an inimitable opening; and all the patients stayed with him, equally grateful that the younger man had full information as to their condition and the remedies best suited to them.—I am, etc.,

London, W.1.

AGNES SAVILL.

Objectionable Certificates

SIR,—Ministers of religion, relieving officers, medical practitioners, and other qualified persons are being asked to sign confirmatory certificates for the Ministries of Pensions and Social Security, the Army, and other departments, in which they are asked to certify that "the claimant is known to me personally and that all the statements in this claim are true to the best of my knowledge and belief." (Forms C.P.1., W.P.1., M.N.1., and O.A.P.17.) I submit that in spite of the saving clause the latter half of this certificate is objectionable because the witness is being asked to warrant the accuracy of the claimant's answers to questions on a wide range of subjects of which the witness cannot possibly be fully informed. A commissioner for oaths will only attest a claimant's declaration on oath that the statements he has made are true. A medical practitioner or other witness should not be asked to combine the roles of guarantor and unqualified commissioner.

In my opinion a suitable formula is that used by the Ministry of Pensions (L.C.109): "I hereby certify that the foregoing declaration was signed this day in my presence and I believe him/her to be the person who he/she represents himself/herself to be. Signed." This certificate should be sufficient to satisfy all parties. The supplementary inquiries found on certain forms as to whether the witness is the claimant's employer, regular medical attendant (A.F.O.1842A), or practising within five miles of the claimant's residence are completely irrelevant and unnecessary.—I am, etc.,

Leeds.

J. H. E. MOORE.

Physiology of Vision

SIR,—I really must protest against the travesty of my discoveries presented by Prof. H. Hartridge (Sept. 28, p. 473). I discovered that the responses of the "eye" to its natural stimulation by light had their parallels in the stimulation of beating hearts by drugs. Previous to Burridge it was firmly believed that these parallels ought to be found in the phenomena elicited by the application of electric currents to the frog's muscle-nerve preparation. Actually the parallels were never found, with the result that a science of visual stimulation has grown up which is a collection of conflicting theories, each of which attempts to rationalize some one fact of visual stimulation with the assumption that a parallel ought to be

found in that muscle-nerve preparation. When I first made that discovery the stimulating drugs were unknown. It now seems likely that acetylcholine functions as the drug in respect of the central nervous system, and that some of the "drugs" produced by the action of light on visual purple stimulate the end-organs of the eye. But, judging by the theories produced, many physiologists still believe that a drug "ought" to act like an electric current.

Having found that a retinal end-organ behaved like a beating heart, I tried out the possibilities that amplitudes determined brightness and rates determined colour, and they worked. Granit is now proving that rates and colours are associated. But also, if "eyes" behaved like beating hearts, it should be possible to augment strengths and slow rates as well as to augment and quicken. When I first used these facts not enough was known about visual purple to make full use of it. Now I teach my students that it seems to me likely that different lights produce different "visual-drugs" from visual purple and that some of these "drugs" augment and quicken while others augment and slow.

From this new standpoint my students just work things out; they learn in fact to predict colour phenomena. Thus, denoting the normal retinal rate by the letter n , then any colour based on quickened rates becomes denotable by the term $(n+x)$, and any colour based on slowing may have its rate denoted by the term $(n-x)$. My students then just put $(n+x)$ and $(n-x)$ together, as it were, and deduce that every colour "ought" to have an opposite or complement such that when the two act together they should give a common result. What is thereby predicted is; and the student learns in a few lines more about the neutrality of grey or white than can be taught in a whole chapter of attempted explanations.

Prof. Hartridge refrained from accepting the challenge that a valid theory of dark adaptation would provide an explanation of the colours of Benham's top. In contrast with this my students here, in the examination held at the end of their first term of study, were able to give satisfactory replies to a question wherein they were required to show that the existence of dark adaptation was compatible with the artist's division of colours into the warm, cold, and neutral. To Prof. Hartridge such a question could well savour of madness, but my students answered it in a few lines because it was so easy.—I am, etc.,

Rangoon.

W. BURRIDGE.

Micturition after Vaginal Plastic Operations

SIR,—I was interested to read of Mr. A. A. Gemmell's method of dealing with the bladder after vaginal repair operations by the instillation of 0.5% mercurochrome (Nov. 30, p. 833). I have no statistics to offer, but it might be of interest to some were I to detail briefly my post-operative treatment for such cases which I have employed for many years with satisfactory results.

It is impossible to tell beforehand which patient will have reflex retention of urine, but a considerable number do have that complication, so I try to forestall it. After the operation is finished, a single gauze swab soaked in paraffin and flavine is inserted right up to the vault of the vagina as a light pack, the end just protruding from the orifice of the vagina. This is left in for 48 hours. An indwelling rubber catheter is also retained in the bladder for the first 48 hours. A clip is put on the catheter and released periodically. The bladder is never allowed to contain more than a few ounces of urine and is kept well below the normal distension limit. If the bladder is allowed to distend, due to reflex retention, the patient suffers much distress and the operation may be prejudiced by strain on the catgut sutures. If the clip is not released sufficiently frequently, some urine may escape at the side of the catheter and the wound may be wet with urine. It is seldom that patients have any trouble with micturition after the catheter is removed. If this does occur, however, it may be replaced for another two or three days. I am satisfied that there is far less risk of infection of the bladder in this method than if a catheter has to be passed repeatedly, however carefully as to asepsis. An over-distended bladder certainly predisposes to infection. This condition is akin to that found with residual urine.

The paraffin-flavine pack serves five purposes: (1) It is soothing to the tissues. (2) It is antiseptic. (3) It tends to prevent

mediate adhesions from forming between the anterior and posterior wounds. (4) When removed it carries away with it any blood or clots that may be lying in the vagina. (5) It prevents urine from running into the vagina. There is special ability for this to happen when a patient is lying on her back. From the very beginning of the first week in bed the patient is encouraged to move the lower limbs, especially the ankle joints, freely in order to obviate the risk of venous stasis with a possibility of clotting and embolism.

Patients are kept lying in bed after operation, without once rising themselves or being raised, for two weeks. During the third week they are free to sit up in bed. At the end of three weeks they get up. A few days later they are allowed home. They are given special instructions as to carefulness about straining from any undue strains for the next two months. Before leaving hospital they are examined, a finger being inserted into the vagina so that any small plastic adhesion between anterior and posterior wounds may be broken down. Two months after leaving hospital the patient reports for a final examination so that the result may be assessed. I have found at this routine has given excellent results and it is quite simple to carry out as far as the nursing is concerned.—I am, Sir,

Dundee.

A. E. CHISHOLM.

Smallpox in the Vaccinated

SIR,—As a ship surgeon concerned with the vaccination of crews I find myself in agreement with Dr. C. Killick Millard, who recommends (Oct. 12, p. 552) that vaccination of those likely to be exposed to smallpox should be carried out on the principle of "little and often." In the course of about thirty years at sea I have had to deal with smallpox on five occasions, though in only one instance was a member of the crew involved. This latter occurrence led me to reduce the interval between revaccination from two years to one year. I consider early revaccination a necessary and sufficient routine measure for the type of population referred to. Exceptionally, cases of modified smallpox do occur within a year of successful vaccination, and I have encountered instances of successful vaccination repeated within an interval of much less than a year; but the answer to these exceptional cases of comparatively fleeting immunity is not, I think, to reintroduce multiple-mark vaccination for all but to note anyone in whom this tendency is suspected and revaccinate him more frequently.

The duration of immunity after successful vaccination appears to be a personal characteristic (possibly a family one) independent of the number of marks made on vaccinating. On the one hand one finds the man with a small solitary scar made in infancy and conferring lifelong immunity of a high degree, and on the other hand the man with one or both arms pitted with a series of multiple marks in whom immunity must be short-lived.

For the past twenty years I have used the intradermal method of vaccination, and I often find it possible to obtain a successful result by this method when recent attempts by scarification have failed. In dealing with large numbers the method is time-saving as well as economical, as no primary dressing is required. Seamen who protest against revaccination can usually be persuaded to have an immunity test carried out by this method, and infants can often be vaccinated while asleep. Finally, for those interested in the study of immunity reaction the intradermal puncture affords an ideal opportunity of observing the rate of development of the areola and papule, etc. In this connexion I have carried out the procedure on myself on some sixty-odd occasions during the past few years and can testify as to its simplicity, safety, and reliability.—I am, etc.,

Rustington.

A. GARDNER.

Grafts for Fractured Neck of Femur

SIR,—I was greatly interested to see Mr. F. P. Fitzgerald's description (Dec. 7, p. 861) of his instruments and technique for the insertion of chip grafts in fractures of the neck of the femur. For some time I have been thinking and hoping that the superior osteogenic and vascularizing power of medullary grafts from the crest of the ilium would help to reduce the vexing number of cases of non-union and avascular necrosis

seen in these fractures after simple nailing. I was therefore much encouraged to read that Mr. Fitzgerald's results have been very satisfactory, particularly as I have recently had a somewhat similar set of instruments made to my design and have not yet had sufficient time to judge the success of the results.

I use a one-piece pencil graft cut from the iliac crest with a saw made from thin-walled 3/8 in. (0.9 cm.) tubular stainless steel with the teeth cut at one end—i.e., a trepanning saw. With this an excellent graft can be cut in a matter of seconds with the aid of a pneumatic drill. The graft is then slid via a cannula into a tunnel drilled into the head of the femur. I am able to insert both the graft and the nail without having to expose the femur, thus saving time and lessening shock in the most frail and ancient patients.—I am, etc.,

Bedford

G. S. STORRS.

Amoebiasis

SIR,—Dr. G. W. Hayward is to be congratulated on his excellent article on amoebiasis as seen in Italy which was published in the *Journal* of Sept. 28 (p. 457) of this year, and which has only recently reached me. His description of the more chronic and insidious manifestations of amoebiasis is most opportune in view of the large number of troops still returning to the U.K. from amoebic endemic areas. I would, however, beg to disagree on certain points concerning amoebiasis as seen in India nowadays and add a few remarks concerning diagnosis and results of treatment.

In the Far Eastern theatre during days of war frank dysenteric symptoms of amoebiasis were common, due mainly to massive infection often occurring in debilitated personnel and also to concomitant bacillary infection, the role of which will be discussed later. These cases were usually treated with sulphaguanidine either in unit lines, in field ambulances, or casualty clearing stations, with, in the majority of cases, a resultant cessation of diarrhoea. They were then returned to the fighting line only to suffer at a later date the inevitable relapses with diarrhoea, abdominal disturbances, loss of weight, and sometimes hepatitis. Through the long passage back to a base hospital via "normal lines of communication," during which time the patients were often inadequately treated, the disease had ample time to become chronic, the amoebic ulcers being secondarily infected with a variety of pathogenic organisms which seemed to prevent the anti-amoebic drugs from having their full effect. Such cases were eventually evacuated to U.K. having had many courses of anti-amoebic treatment with little effect, until the advent of penicillin plus sulphonamides, which combination clears the large bowel of secondary infection and allows the anti-amoebic drugs their full action. This course now cures the majority of cases. Previously results of treatment in these cases was admittedly poor, and a certain number of them perforated and died of the resultant peritonitis or succumbed to amoebic hepatitis. It must be emphasized that such cases have rarely arisen in India Command either during or since the war, and are now, to the best of my knowledge, seldom seen in any part of the Far Eastern theatre. They were due mainly to the exigencies of war which caused delay in treatment, while part at least of the dysenteric symptoms was due to a co-existing bacillary infection, a finding which has been extremely common. I do not believe that the underlying amoebic infection differs from that seen in other parts of the world, for when early and adequate treatment was given to these cases they almost invariably did well.

The question of mixed infections is one of very considerable importance, and some observers go so far as to say that all cases of amoebic dysentery are primarily associated with a bacillary infection. The sequence of events is as follows. A patient is admitted with diarrhoea, the stools containing blood and mucus. Microscopically, red cells, pus cells and macrophages, Charcot-Leyden crystals, and vegetative *Entamoeba histolytica* are seen. If in order to clear the bacillary infection sulphaguanidine is given, the diarrhoea usually ceases, and, this being very important, red cells, pus cells, and frequently *E. histolytica* disappear from the stools, a point first described by Ransome and Stokes. This disappearance of *E. histolytica* is presumably due to healing of the amoebic ulcers by eliminating the bacillary element. It is therefore of fundamental importance that even a seemingly straightforward

case of bacillary dysentery occurring in endemic amoebic areas should have very careful stool and sigmoidoscopic examination to ensure that no amoebic element exists. If this is omitted the patient will often be readmitted after a few weeks with the more insidious forms of amoebiasis.

To-day the type of case most commonly seen in India is that described by Dr. Hayward—the chronic case in which ill-health insidiously attacks the patient almost without his knowledge. Vague abdominal symptoms, of which flatulence and a sense of fullness occurring after a few mouthfuls of food are common; abdominal pain or discomfort, usually in the right iliac fossa and never severe; loss of weight, which is not rapid but which is in some cases as much as 1-1/2 stone (6.3-3.1 kg.); tiredness, lassitude, irritability, and lack of concentration: these are the commonest symptoms. Diarrhoea is seldom complained of, and a history of a certain periodic looseness of the bowels is only elicited on direct questioning. On examination patients look tired and unwell, the loss of weight often showing itself most noticeably in the face. The most valuable physical sign, as stressed by Dr. Hayward, is thickening and tenderness of the caecum and ascending colon, which sometimes can only be ascertained by deep palpation. Patchy tenderness over various parts of the colon has not been seen. Sigmoidoscopy has been very helpful, though the number of cases in which vegetative or cystic forms of *E. histolytica* have been found in a sigmoid swab when absent from the stool has been negligible. The changes seen in the rectal mucosa are more valuable pointers to the diagnosis. Stool examinations have not been so successful as in Dr. Hayward's cases, although I have not adopted so rigorous a means of purgation, having found that one or two large doses of salts early in the morning are sufficient to produce several watery stools.

Although positive stools have been found in the majority of cases, a group remains in which, from all points of view, the diagnosis of clinical amoebiasis seems justified. They presented the typical picture of chronic amoebiasis as previously described, but with entirely negative stools repeated up to a dozen times following purgatives, and an entirely normal rectal mucosa. These cases seemed to be caused by a very chronic amoebic infection strictly localized to the caecum. At first one was chary of giving these patients a course of treatment lasting for a month, but, having seen the dramatic improvement which has occurred in all cases so treated, there is now no hesitation in starting treatment in any case in which one feels certain of the diagnosis of amoebiasis, despite negative laboratory findings. I speak with some feelings on this point, having myself experienced the welcome return of well-being after treatment, which was not in my case aided by bed-rest.

Treatment has been along the lines laid down by the Army in India—i.e., "diodoquin" tabs., 3 t.d.s., days 1 to 20; emetine, 1 gr. (65 mg.) intramuscularly, days 1 and 2; emetine bismuth iodide, 3 gr. (0.2 g.) at night, days 3 to 14; carbarsone, 4 gr. (0.25 g.) b.d., days 15 to 20. This treatment has been entirely satisfactory, and since its adoption approximately one year ago I have not yet seen a single relapse. There is no doubt that the adoption of "diodoquin" in place of retention enemata has made treatment far easier for the patient and nursing staff and far more effective.

I would end by again stressing (and it cannot be stressed too often) the utmost importance of realizing the existence of these chronic forms of amoebic infection and of investigating them on the lines suggested by Dr. Hayward in his paper. In this way much chronic ill-health and many cases of amoebic hepatitis may be avoided.—I am, etc.,

FRANCIS T. PAGE,
Capt., R.A.M.C.

Namkum, India.

Prevention of Infant Deaths

SIR,—I have read with great interest Dr. J. Tudor Lewis's excellent and informative article on the prevention of infant deaths (Dec. 14, p. 893). I agree with Dr. Lewis that there is need for the closest co-operation between maternity units, hospital, and home services, and I commend the trial scheme which he has described.

In connexion with the cases quoted it would be interesting to know the weight of each of the seven infants on discharge from the hospital or maternity unit. This information would enable one to assess whether these infants might well have been

kept in hospital for a longer period. This applies in particular to the five of the seven cases which were premature or immature, for it has been my practice to keep such premature infants in hospital until a weight of seven pounds has been reached; thus one is assured that the infant is robust on discharge and has a better chance of survival than if it is discharged when it has regained its mere birth weight.

Respiratory complications arose in four infants. It is well known that partial atelectasis tends to occur in weakly and premature infants. Moreover, respiratory infection of a latent or chronic type is so often missed because the clinical picture is dominated by dietetic difficulties and there is little, if any, rise in temperature. I would stress therefore the importance of *regular clinical examination of the lungs during the time the infant is in hospital*. One finds so often evidence of a patchy bronchitis, or occasionally more ominous localized patches with sharp crackling rales suggestive of an early pneumonic consolidation. Regarding Case 7 it is stated: "Antenatal clinic attended regularly," and later: "Mothercraft not very good." To my mind this is an important point and shows how hospital antenatal clinics concentrate unduly on the obstetric and medical aspects of pregnant women, neglecting the ever-important principle of teaching mothercraft during the antenatal period.

More emphasis should be placed on teaching the mother in her home, and health visitors should be especially trained in paediatrics, visiting homes more frequently than is the custom and having the fullest co-operation of the family doctor. It is in this latter respect that much improvement could be effected and the mutual antagonism existing so often between the family doctor and health visitor be eliminated. Perhaps medical officers of health might consult their local authorities to consider the advisability of setting up a panel of general practitioners in the district with special experience of paediatrics; who would be willing to visit and treat infants in their homes when the health visitor is not satisfied with the progress of such infants. The work of this group of doctors could be enhanced by including in this panel consulting hospital paediatricians whose clinical knowledge of the infant would render great service to the scheme. The realization by the public health authorities, and indeed by the medical profession as a whole, of the efficient co-ordination of all services vital to the well-being of the mother and her newly-born infant will be a big step forward towards the ideal we seek to attain. Until this is generally accepted we cannot hope for any noticeable improvement.—I am, etc.,

Leeds.

ISAAC ROSE.

Gastro-enteritis in Maternity Hospitals

SIR,—Publicity has recently been given to outbreaks of gastro-enteritis in the nurseries of some maternity hospitals. An outbreak of apparently similar nature occurred in the autumn of 1944 at the Royal Hampshire County Hospital at Winchester. Careful investigations by the research laboratory failed to disclose the causative organism, and it was presumed to be a virus infection. In spite of treatment which included blood transfusions by various routes we had a number of deaths among those infected, particularly the premature infants. Finally it was decided to employ sulphonamide medication, and in view of the gastric disturbance it was felt that probably sulphadiazine would be most easily tolerated. The dosage given was one-sixteenth of a gramme every four hours combined with alkalis. The effect was quite remarkable, and the remaining cases cleared up within the course of two or three days. After dealing with one or two further incipient cases the epidemic completely subsided. I think our experience at the hospital may be of use in dealing with similar outbreaks, and it is a treatment that I should not hesitate to employ should we have the misfortune to have any recurrence of this very disquieting disorder.—I am, etc.,

Winchester.

Scottish Depot: 665, Great Western Road, Glasgow, W.2.

children against whooping-cough as soon after admission as practicable, using a stock vaccine and giving three injections of 1 ml. at weekly intervals followed by a fourth after a further four weeks. Where children have not been previously immunized against diphtheria I have combined the third and fourth doses with the appropriate dose of A.P.T.

In spite of the fact that there has been a considerable and prolonged epidemic of whooping-cough in the district, to which the children have been exposed by contact in school, and that at least two new admissions were found to be in the acute stage of whooping-cough, we have not had a single case among the inoculated children.—I am, etc.,

Harrogate.

H. CRAVEN PETCII.

Marasmius oreades, an unrelated species which is responsible for the familiar rings.

For many years now a common English plant with a common English name has masqueraded in medical literature under the horrible Americanism "alfalfa." And only the other day I heard one of the leaders of our profession express surprise that our native *Senecio jacobaea* does not cause hay fever, like the North American species which shares its vulgar name. For much that comes to us across the seas we should be grateful, but may we not keep our own names for our own plants? One other point: is not the inclusion of *Clitocybe* and *Buellia* among the higher plants an unmerited promotion?—I am, etc.,

London, S.E.1.

C. P. PETCH.

Lactic Acid Injections in Osteoarthritis

SIR,—During the last year I have treated over 60 osteoarthritic joints with lactic acid and have had most encouraging results. The knee- and shoulder-joints are very quick to improve, but it is only fair to warn patients with advanced hip disease that any improvement must take a considerable time.

Dr. Mawson's statement (Nov. 9, p. 691) that up to six injections are given if needed is very misleading. In the twenty or so hips I have treated it is only in the very early cases that any rapid improvement has been obtainable. I feel sure that Mr. Grant Waugh (Dec. 7, p. 876) will agree that severe hip-joints with cartilage destruction and mushrooming of the head of the femur will require an injection once a fortnight for a year or more before any permanent benefit can be expected.—I am, etc.,

London, W.1.

VERNON HETHERINGTON.

"Analgesic" or "Anaesthetic"?

SIR,—Dr. J. N. Fell (Nov. 9, p. 711) has registered a protest against the use of the term analgesic. I believe that the exclusive use of this word whenever applicable would be rather pedantic, and I am not aware that there is in fact any real attempt to substitute it for the more commonly used term anaesthetic. Macintosh and Mushin, in the preface to their book, *Local Anaesthesia of the Brachial Plexus*, explain that although analgesia is the more accurate word, they frequently use the more comprehensive term.

Dr. Fell has accurately defined the two words, but thereafter his reasoning seems rather faulty. "Novocain" and cocaine and other local anaesthetic agents do not abolish all sensation in the affected area. They do abolish pain, and are therefore true analgesics: they do not abolish touch, deep pressure, and thermal sensibility, and are not therefore strictly anaesthetics. No one expects a local anaesthetic agent to abolish sensations outside the local area in which they are acting; it is therefore irrelevant to argue that they do not normally affect sight, hearing, or consciousness. Neither analgesia nor anaesthesia implies loss of motor conductivity, and the occurrence of this phenomenon is not used as an argument justifying the use of either term.

I frankly do not understand what Dr. Fell means by intravenous general analgesia. I hope he is not referring to intravenous barbiturates, for these drugs are hypnotic, sedative, and anaesthetic, but not analgesic. The only intravenous general analgesic in common use is intravenous morphine. It is a well-established fact that the first stage of general anaesthesia, except with the barbiturates, is a state of analgesia. For some unknown reason Dr. Fell calls this fact a crowning absurdity. Finally, is analgesia such an ugly word? It is surely less likely to be mispronounced by the laity than anaesthesia and its derivatives.—I am, etc.,

London, W.1.

F. W. ROBERTS.

Plant Names

SIR,—The identification of the larger fungi is not of much practical importance until one is faced with a case of fungus poisoning, and Dr. P. D'Arcy Hart's most interesting Mitchell Lecture (Nov. 30 and Dec. 7) does not show much use for them as a source of antibiotics. But may I nevertheless make a small protest against his description of *Clitocybe gigantea* as the "fairy-ring mushroom"? In England this name belongs to

Age Limit in Advertisements

SIR,—Frequently there appear in the *Journal* and other papers advertisements inviting applications for whole-time posts under the various Ministries. To quote the wording: The posts are permanent and pensionable in accordance with the general rules governing the grants of pensions in the Civil Service. Candidates must be under 45 and preferably younger. The salary offered is £1,150 to £1,500.

There must be many men and women who after a hard life in general practice would be glad to apply for such posts but are barred by the age limit imposed. These doctors would be quite capable of doing the work from a physical point of view and have, moreover, years of experience behind them, not only of the special work appertaining to the particular post but in dealing with the psychology of the individual. I am of course fully aware that for superannuation one must enter any scheme at 45 or under, but surely this difficulty as far as the medical world is concerned could be surmounted. I feel sure that many doctors over the above age limit would be glad to have a sure income and lighter work without any question of superannuation, especially if they were offered the maximum salary on taking over the post. They could hold the post while physically fit or retire at their own option. Gradually, as time will take its usual toll, vacancies could then go to the younger people.

Under the new Health Act and the Industrial Injuries Act there will be, necessarily, scores of whole-time posts created, and under the present regulations these posts will go to the younger men, leaving the older ones to work the Acts (always presuming they will be worked) as best they can under their own physical limits. This surely is not going to benefit the public when it has been stated that at least 50,000 doctors will be required to work the National Health Act efficiently. Less than half that number are available and the required number will not be reached for years. Why then should an age limit be applied?

I myself am well over the age of 45, but physically fit, with many years of general practice, including hospital appointment as physician in charge of out-patients, and referee to many industrial and life assurance companies. It may be asked why I do not retire. The simple answer is that I cannot afford to do so owing to the economic conditions of to-day. I am not anxious to take service under the Act as a general practitioner, but I shall be compelled to do so since any compensation I may receive for my practice would be quite insufficient to keep me in my present standard of living. There may be many doctors in like circumstances, and I visualize that we shall have to keep on working in a general practice and so shorten our days unless we are given the opportunity of living longer by obtaining a whole-time post with its lighter work. I think this is a matter which should engage the attention of the Council of the Association, and especially of the Negotiating Committee if and when they do negotiate.—I am, etc.,

DUNMAR.

A circular from the Ministry of Health points out that local authorities should not disregard family allowances when assessing the resources of applicants for relief under the Blind Persons Act, or for tuberculosis allowances, or for any purpose for which the assessment varies with the size of the applicant's family. The National Health Service and the National Insurance Scheme are designed to eliminate any apparent anomalies that may exist, but until they come into operation double allowances should be avoided.

Obituary

A. R. NELIGAN, M.D.

We regret to announce the sudden death on Dec. 8 of Dr. A. R. Neligan, who in later life was well known as a spa physician at Droitwich, but before then had been for twenty years physician to the British Legation in Tehran.

Anthony Richard Neligan, son of J. W. Neligan, M.D., was born in 1879 at Tralee, Co. Kerry. He was educated at Whitgift School and St. Bartholomew's Hospital, where he had a distinguished career, winning the Brackenbury scholarship in medicine, the Matthews Duncan gold medal and prize in obstetrics, the Skynner and Burrows prizes in pathology. He graduated M.B.Lond. in 1903, and after serving as house-physician to Sir Norman Moore and Sir Archibald Garrod became interne gynaecological assistant under Sir Francis Champneys. He had been honorary secretary of the Hospital Amalgamated Clubs and later one of the three founders of the Students' Union. He represented Bart's, the United Hospitals, and Surrey County at rugby football. In 1906, after taking his M.D. and while demonstrator of pathology under Sir Frederick Andrews, Neligan was appointed by the Foreign Office to the post at Tehran on the death of D. F. Odling, who had spent thirty years in Persia. Neligan found the professional and social life in Tehran most interesting; it included service at the Legation dispensary, where poor Persians had received free treatment for more than a century, and consulting work among Europeans and Persians. He started the first pathological laboratory in the capital and carried out all the clinical pathology. For twenty years he had a place as the British representative on the Persian Sanitary Council and was its vice-president for a year. He did especially good work in the prevention of malaria and small-pox, and was first director of the public vaccination service. The village of Gulahek, where the Legation spent the summer, came to be spoken of as a sanitary model for the country. In the war of 1914-18, during which he was retained in Persia by our Foreign Office, Neligan was lent, with his friend J. S. Scott, to the Persian Government to reorganize its hospital at Tehran. He was a founder and first secretary of the Tehran Medical Society and adviser to the Legation on Persian opium traffic. When he retired in 1926 he received the thanks of the Secretary of State. On returning home he took up the study of chronic rheumatic conditions, visited medical centres in Europe, the U.S.A., and Canada, and made lasting contacts with men of like interests. As its first superintendent he helped to organize the Red Cross Clinic for Rheumatism in Regent's Park (1930), and later settled at Droitwich in spa practice and took part in the proceedings of British and international societies concerned with rheumatism and physical medicine. At Droitwich he was honorary physician to the Royal Brine Baths Clinic, and chairman of the fund for treatment of rheumatism in poor persons. He was a medical officer in the Home Guard during the last war and a member of the Worcester Medical Board.

Neligan joined the B.M.A. in 1920, he served on the Spa Practice Committee for several years, and was a member of the Rehabilitation Committee up to the time of his death; he also served on the Spa Practitioners Group Committee from 1934 onwards. A man of most kindly and courteous nature, he will be much missed by many friends. Bart's has had no more loyal son, and his election as a governor gave him great pleasure.

On Jan. 1, 1947, an Order-in-Council will bring under the control of the Dangerous Drugs Act the following drugs and preparations which have not hitherto been so controlled. Dihydrodesoxymorphine (commonly known as desomorphine), pethidine (1-methyl-4-phenylpiperidine-4-carboxylic acid ethyl ester), or any preparation, not being a preparation capable of external use only, made from extract or tincture of Indian hemp. From Jan. 1 next, therefore, it will be unlawful for any person who is not authorized to manufacture, supply, procure, or possess any of these drugs. Doctors and retail chemists should therefore be careful to comply with the regulations regarding the issue of prescriptions and the keeping of registers in respect of these drugs.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The following appointments to posts in the Department of Biochemistry and Pathology in connexion with Addenbrooke's Hospital have been made from Oct. 1, 1946: University biochemist to the hospital, N. R. Lawrie, Ph.D.; university morbid anatomist and histologist, A. M. Barrett, M.B., B.Chir.; university bacteriologist, M. H. Gleeson White, M.B., B.S.Lond.

The forthcoming appointment of a Huddersfield lecturer in special pathology is announced in the *University Reporter*. The person appointed will be required to undertake research and give instruction on viruses and on diseases produced by viruses. Candidates should send their applications to the secretary of the Appointments Committee of the Faculty of Biology "B" at the Department of Pathology, Tennis Court Road, Cambridge, to reach him by Feb. 1. Further information about the duties and conditions of the post may be had from Prof. H. R. Dean at the Department of Pathology.

UNIVERSITY OF SHEFFIELD

The following appointments were made at a meeting of the University Council held on Dec. 13: *Lecturer in Physiology*, Q. H. Gibson, M.D., Ph.D. *Lecturer in Medicine for Dental Students*, W. D. Wallace, M.Sc., M.B., Ch.B. *Lecturer in Surgery for Dental Students*, M. F. A. Woodruff, M.D., M.S. *Assistant Tutor in Medicine at City General Hospital*, K. J. G. Milne, M.D.

UNIVERSITY OF EDINBURGH

At a Graduation Ceremonial on Dec. 13 the following degrees were conferred:

M.D.—M. W. Archdall, ²L. F. Brown, ²E. M. Donaldson, ²J. Greenstein, ²A. F. Lang, ²T. Macleod, ²I. R. Milne, ²R. W. G. Ramsome-Wallis, ¹G. D. F. Steele.

D.Sc.—*Department of Pure Science*: Lydia D. Parsons, M.D. M.B., Ch.B.—H. I. O. Armstrong, G. H. Blair, J. Calder, G. R. Duffes, Janet T. Y. Forrest, Mary G. Forsyth, G. R. C. D. Gibson, A. C. Jacob, Muriel G. James, D. L. Kirk, W. H. Lloyd, J. M. Loughran, N. C. Low, A. MacLennan, Jean C. I. Melville, Catherine S. Paterson, J. P. Payne, J. C. Phemister, K. Robertson, C. M. C. Smelt, Anne M. Stewart, I. C. Wilson, ²J. H. Young.

The following degrees were conferred in the Polish School of Medicine at Edinburgh:

M.D.—A. J. Baranski, J. F. Majeranowski. M.B., Ch.B.—B. Adamski, S. Dyakowski, M. Gonszor, A. Jarosz, A. Kepinski, J. Klimczynski, T. Klosowski, J. K. Koziol, J. G. Lipski, W. Milius, Z. Prokopowicz, Anna M. Sokolowska, M. Szamocki, Z. Teleszynski, J. Wilczynski, Hanna H. Wozniak, S. Wozniak, W. Zaleski, W. Zarski.

¹Highly commended for thesis. ²Commended for thesis. ³In absentia.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At an ordinary meeting of the Council of the College, held on Dec. 12, with Sir Alfred Webb-Johnson, Bt., President, in the chair, Prof. Ian Aird, F.R.C.S.Ed., was admitted *ad eundem* to the F.R.C.S.Eng.

The Hallett Prize was presented to Mr. R. P. Melville (Sydney). Mr. J. G. Turner and Prof. Evelyn Sprawson were elected Charles Tomes Lecturers for 1947.

Mr. P. H. Mitchiner was appointed editor of the forthcoming College publication.

A diploma of Membership was granted to E. N. Rees (Cardiff). Diplomas of Fellowship were granted to the following successful candidates:

A. G. Tresidder, J. Penry, D. B. Cater, T. Derneess, W. G. France, J. A. R. Johnson, C. M. Dransfield, M. A. Margo, J. W. M. Leslie, J. A. Rhind, W. D. Doey, K. H. Taylor, J. A. S. Green, C. A. Jackson, R. G. Robinson, D. H. Thompson, T. H. Cullen, J. S. McConnachie, K. W. Martin, A. J. Walker, F. H. D. Hutter, G. K. Rose, G. E. Stein, L. R. S. Taylor, C. E. Drew, H. H. G. Eastcott, A. Klidjian, P. C. Walsen, T. L. Kennedy, H. W. A. Baron, A. Jolleys, C. O. Fung-Kee-Fung, A. M. Wood, L. L. Bromley, I. A. Alexander, A. H. M. H. Ashoor, C. H. Bartlett, S. K. Burcher, M. Burdman, H. A. Daniels, J. B. Dowe, H. B. Hattam, L. H. Hiranandani, E. S. R. Hughes, H. Ibrahim, D. S. Iyer, D. R. Leslie, L. Loewenthal, S. D. Loxton, A. B. McCarten, R. J. Maneksha, R. Marcus, K. W. Priddis, J. G. Pyrer, R. F. Read, W. S. Rees, D. B. Robertson, D. R. Ryder, V. S. Sheth, F. N. Street, J. M. Tyler, S. A. Vincent, Muriel C. Waterfall, T. E. Wilson.

Diplomas in Anaesthetics were granted, jointly with the Royal College of Physicians of London, to the following successful candidates:

E. F. Adams, S. N. Albert, G. S. Ambardekar, J. D. M. Barton, W. L. Bilsland, R. P. Bliss, N. H. Bloom, R. A. Bowen, D. M. Brown, C. A. Cheate, H. C. Churchill-Davidson, R. E. W. B. Comerford, R. L. Coulter, J. I. Davies, W. W. Deane, A. G. Doughty, G. L. Evans, H. Fairlie, D. J. H. Goodhead, Helen E. Gordon, R. W. G. Grindlay, J. R. Hamerton, G. Herington, M. H. W. Holloway, G. Houseman, M. S. Howe, J. McN. Inglis, R. G. Jones, W. A. Jones, F. M. Lancaster, R. A. Lattey, J. D. Louchrey, T. H. McCall, I. M. McCully, A. I. MacKenzie, J. Maisher, Julia M. Middleton, M. Nash, J. North, J. R. Odell, H. F. Patrick, A. W. Raffan, G. A. Rawlins, D. F. Rees, G. J. Rees, T. B. L. Roberts, Eleanor H. Russell, L. T. Scott, J. J. Slowe, J. Sironen, E. I. Tate, W. N. Vellacott, G. L. Way, J. H. Willis, F. G. Wood-Smith, S. D. Young.

No. 49

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Dec. 7.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or to return available.

Disease	1946					1945 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

Annual rate per 1,000 persons living	—	—	23.3	—	—	—	17.1	22.6	—	—
Stillbirths	264	24	65	—	202	32	27	—	—	—
Rate per 1,000 total births (including stillborn)	—	—	53	—	—	—	31	—	—	—

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

It is still not possible to publish the return of births and deaths for Eire for the weeks ended Oct. 26, Nov. 2, 9, 16, 23, 30, and Dec. 7.

EPIDEMIOLOGICAL NOTES

Neonatal Diarrhoea and Enteritis

Outbreaks of neonatal diarrhoea and enteritis have been reported from several widely separated institutions. Diarrhoea and enteritis is not notifiable, and how much the newly born have contributed to the recent rise in mortality cannot be determined until deaths by ages are available. Deaths from this cause in the 126 great towns increased during the 45th week of this year from 31 to 57, and small increases have been noted in subsequent weeks until 69 deaths were recorded in the 49th week. The number of deaths in recent weeks is above the total for the corresponding period of the preceding years, although the figures for earlier weeks had been considerably below the corresponding figures for previous years. A comparison of the deaths in the recent weeks with those of the same weeks in the two preceding years shows this trend:

Deaths from Diarrhoea and Enteritis in Infants under 2 years in the 126 great towns

Weeks	1946	1945	1944
35-39	201	363	386
40-44	198	269	239
45-49	317	177	200

In other words, the Registrar-General's figures for the first eleven weeks of the December quarter do not show any notable increase of mortality from enteritis and diarrhoea. In the 126 great towns, including London the average number of deaths of infants under 2 years of age per 1,000 births for the December quarter 1946 to date was 5.8. The comparative figure for the same period of 1945 was 6.8.

Outbreaks recently reported from maternity homes and institutions in various parts of the country are not all of the same clinical type. The most serious appears to have been that at two hospitals in Leicestershire, with between 40 and 50 cases among infants and 23 deaths. In its high case mortality and relative lack of associated illness in adults this outbreak resembles incidents already recorded in America (Frant, S., and Abramson, H., *New York State J. Med.*, 1939, 39, 784) and also in this country (Sakula, J., *Lancet*, 1943, 2, 758). Clinically this condition usually begins during the first three weeks of life with a sudden weight loss which may precede obvious gastro-intestinal upset by several days. Pyrexia is not a marked feature, but the subsequent course suggests an intense toxæmia. In any particular institution the beginning of such an outbreak may not be explosive, there being intervals of a week or so between the first cases. Breast-feeding does not always protect, but the breast-fed infant usually appears to stand a better chance of survival. Pathological and bacteriological investigations have hitherto proved entirely negative. The only effective measure of control is closure of the ward or nursery concerned.

In the outbreak reported in connexion with a maternity home at Preston the illness of the 18 fatal cases started at varying intervals after discharge from the home, and the trouble began as long ago as August. It is not at present possible to state the case mortality of this outbreak, which presents some unusual clinical features that are being investigated by a team of paediatric specialists.

The illness among infants reported from institutions in several other areas differs clinically from that at Leicester and at Preston and appears to be much less severe. Usually mothers and nursing staff have been affected as well as infants. In one outbreak at Hull it is possible, though not yet confirmed, that the cause was a *Salmonella*.

Discussion of Table

In England and Wales increases were recorded in the notifications of measles 461, dysentery 18, and diphtheria 12, while decreases were reported for scarlet fever 106, whooping-cough 95, and acute pneumonia 68.

The fall in the incidence of scarlet fever was mainly contributed by the West Midland counties, but no county showed a large deviation from the total of the preceding week. The only change of any size in the local returns for diphtheria was an increase of 12 in Lancashire; the city of Liverpool accounts for half the notifications of diphtheria in this county and for one-eighth of the total for the whole country. The returns for whooping-cough rose slightly in the southern section of the country but fell in the north; the largest decline was Lancashire 56. The largest rises in the notification of measles were Glamorganshire 99, Middlesex 89, Lancashire 80, Northumberland 79, and Staffordshire 62: the only significant decline was Kent 90.

A fresh outbreak of dysentery involving 14 persons was reported from Durham (Chester-le-Street U.D. 10). The only other large centre of dysentery was London 13.

In *Scotland* the principal changes in the trends of infectious diseases were a rise of 51 for scarlet fever and a decrease of 106 for measles. Of the total of 360 cases of scarlet fever 156 were recorded in the city of Glasgow.

In *Eire* the chief features of the returns was a rise of 31 in the notifications of whooping-cough and an increase of 10 for diarrhoea and enteritis. Of the 87 cases of whooping-cough 38 were recorded in Dublin C.B., and 26 in the rural district of Youghal No. 2, Waterford.

In *Northern Ireland* an increase of 73 was recorded in the outbreak of measles in Belfast C.B.

No returns are available for week ended Dec. 14.

Medical News

Abstracts of World Medicine and Abstracts of World Surgery, Obstetrics and Gynaecology, will make their first appearance in January, 1947. These two new journals are being published monthly by the British Medical Association, the first at an annual subscription of 3 guineas and the second at 2 guineas. Applications for subscription should be sent to: The Publishing Manager, *British Medical Journal*, B.M.A. House, Tavistock Square, London, W.C.1.

The annual general meeting of the Medical Society of the L.C.C. Service will be held at the County Hall, Westminster Bridge, S.E., on Wed., Jan. 8, 1947, at 4.30 p.m., when Mr. G. F. Stebbing will give an address on "The Organization of Cancer Treatment."

A course of twelve lectures on "Recent Advances in Dairy Technology" will be given at the Central Laboratories, Express Dairy Company, 133, Euston Road, N.W., under the auspices of the Chelsea Polytechnic, on Tuesdays at 6.30 p.m., from Jan. 14 to April 1. On Jan. 7, at 6.30 p.m., Dr. N. C. Wright, director of the Hannah Dairy Research Institute, will deliver an inaugural lecture on "The Production and Handling of Milk and Milk Products in Sub-tropical and Tropical Countries." The twelve lecturers include Dr. S. K. Kon, who will speak on "The Nutritive Aspects of Milk and Milk Products" on Feb. 4; Prof. G. Selby Wilson, who will discuss "Diseases Caused by Dairy Products" on March 18; and Dr. W. A. Lethem on "The Ministry of Health in Relation to the Dairy Industry," on March 25. The fee for the course is £1 1s., which should be sent to the Principal, Chelsea Polytechnic, Manresa Road, Chelsea, S.W.3.

The annual congress of the Ophthalmological Society of the United Kingdom will be held at Glasgow on March 27, 28, and 29, 1947, when the president will deliver an address entitled "De Senectute." The subject for discussion will be "Rhinology in Relation to Ophthalmology," to be opened by Mr. John Marshall, Mr. Gilbert H. Howells, and Dr. R. McWhirter. Members who wish to read papers are asked to send the titles to Mr. E. F. King, F.R.C.S., 79, Harley Street, London, W.1., as soon as possible. Abstracts of papers should be submitted by January 31, 1947. The annual dinner of the society will be held on March 27, and on March 28 there will be a clinical meeting at Glasgow Eye Infirmary. The afternoon of March 29 visits have been arranged to the Glasgow Art Galleries, Kelvingrove, and to the Hunterian Museum at the University of Glasgow.

The Council of the Royal Medical Foundation of Epsom College will, in March, 1947, award a pension of at least £30 per annum to a necessitous medical man, fully 55 years of age, who has been registered for five years. Forms of application may be had from the Secretary, Epsom College, Surrey, and must be returned by Jan. 30, 1947.

A combined clinico-pathological meeting was held on Nov. 29 at the Durham County Hospital. A pathological exhibition demonstrated B.M.R. determination, haemoglobinæmia, dysentery due to *B. dysenteriae flexneri* "W," and a case of chorionepithelioma presenting certain curious anomalies.

Dr. E. H. R. HARRIES, at a meeting of the Medical Society of the L.C.C. Service at the North Eastern Fever Hospital on Dec. 5, outlined changes in the service since 1890 when compulsory notification had led to its establishment. In increasing measure the older main causes for admissions—scarlet fever, diphtheria, and the enteric group—were being replaced by children's measles, whooping-cough, and gastro-enteritis. Isolation of cases until diagnosed and avoidance of cross-infection determined hospital planning. The specialties in his hospital were now in the hands of experts and the frequent presence of students—undergraduate and postgraduate—was most stimulating to the staff.

The British Empire Cancer Campaign's Garton Medal and prize for 1946 were presented at the annual meeting on Dec. 19 to Prof. E. L. Kennaway.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Atiology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate, Westcent, London*. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra, Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

—Regeneration of Divided Nerves

Q.—What is the physiological mechanism of regeneration from the proximal end of a divided nerve fibre? Do nerve fibrils split and thus reduplicate themselves?

A.—When a nerve fibre is divided the peripheral part degenerates; the axon and myelin sheath are removed by phagocytosis and all that remains is an empty tube composed of Schwann cells, the bodies of which form the wall of the tube, enclosed by a thin collagenous envelope called the endoneurium. If the injury has been at all violent there is more or less degeneration on the central side of the break this is sometimes called retrograde degeneration but does not differ in any way from the degeneration that occurs distally. Regeneration starts surprisingly early, probably within twenty-four hours, and consists of an outflowing of axoplasm from the central end of the divided axon. The substance of the axoplasm behaves as if it were a viscous fluid, and the line of flow, like those of a stream of lava, are determined largely perhaps exclusively, by mechanical factors. Thus it is usual to find a number of streams of axoplasm, often twenty or more, flowing out from one divided axon, and these streams will divide and join again according to the obstructions they encounter. Their ultimate fate depends upon the nature of the injury, and here we must turn from consideration of the isolated fibre to that of the nerve as a whole.
